- Volume 1 H. L. Clever, *Helium and Neon*
- Volume 2 H. L. Clever, *Krypton, Xenon and Radon*
- Volume 3 M. Salomon, *Silver Azide, Cyanide, Cyanamides, Cyanate, Selenocyanate and Thiocyanate*
- Volume 4 H. L. Clever, *Argon*
- Volume 5 R. Battino, *Oxygen and Ozone*
- Volume 6 J. W. Lorimer, *Alkaline-earth Metal Sulfates*
- Volume 7 E. M. Woolley, *Silver Halides*
- Volume 8 P. Farrell, *Mono- and Disaccharides in Water*
- Volume 9 R. Cohen-Adad, *Alkali Metal Chlorides*
- Volume 10 J. E. Bauman, *Alkali Metal and Alkaline-earth Metal Oxides and Hydroxides in Water*
- Volume 11 B. Scrosati and C. A. Vincent, *Alkali Metal, Alkaline-earth Metal and Ammonium Halides. Amide Solvents*
- Volume 12 Z. Galus and C. Guminski, *Metals in Mercury*
- Volume 13 C. L. Young, *Oxides of Nitrogen, Sulfur and Chlorine*
- Volume 14 R. Battino, *Nitrogen*
- Volume 15 H. L. Clever and W. Gerrard, *Hydrogen Halides in Non-aqueous Solvents*
- Volume 16 A. L. Horvath, *Halogenated Benzenes*
- Volume 17 E. Wilhelm and C. L. Young, *Hydrogen, Deuterium, Fluorine and Chlorine*
- Volume 18 O. Popovych, *Tetraphenylborates*

A further 60-80 volumes are in progress to complete the Series.

### NOTICE TO READERS

Dear Reader

If your library is not already a standing-order customer or subscriber to the Solubility Data Series, may we recommend that you place a standing order or subscription order to receive immediately upon publication all new volumes published in this valuable series. Should you find that these volumes no longer serve your needs, your order can be cancelled at any time without notice.

## FOREWORD

*If the knowledge is  
undigested or simply wrong,  
more is not better*

How to communicate and disseminate numerical data effectively in chemical science and technology has been a problem of serious and growing concern to IUPAC, the International Union of Pure and Applied Chemistry, for the last two decades. The steadily expanding volume of numerical information, the formulation of new interdisciplinary areas in which chemistry is a partner, and the links between these and existing traditional subdisciplines in chemistry, along with an increasing number of users, have been considered as urgent aspects of the information problem in general, and of the numerical data problem in particular.

Among the several numerical data projects initiated and operated by various IUPAC Commissions, the *Solubility Data Project* is probably the most ambitious one. It is concerned with preparing a comprehensive critical compilation of data on solubilities in all physical systems, of gases, liquids and solids. Both the basic and applied branches of almost all scientific disciplines require a knowledge of solubilities as a function of solvent, temperature and pressure. Solubility data are basic to the fundamental understanding of processes relevant to agronomy, biology, chemistry, geology and oceanography, medicine and pharmacology, and metallurgy and materials science. Knowledge of solubility is very frequently of great importance to such diverse practical applications as drug dosage and drug solubility in biological fluids, anesthesiology, corrosion by dissolution of metals, properties of glasses, ceramics, concretes and coatings, phase relations in the formation of minerals and alloys, the deposits of minerals and radioactive fission products from ocean waters, the composition of ground waters, and the requirements of oxygen and other gases in life support systems.

The widespread relevance of solubility data to many branches and disciplines of science, medicine, technology and engineering, and the difficulty of recovering solubility data from the literature, lead to the proliferation of published data in an ever increasing number of scientific and technical primary sources. The sheer volume of data has overcome the capacity of the classical secondary and tertiary services to respond effectively.

While the proportion of secondary services of the review article type is generally increasing due to the rapid growth of all forms of primary literature, the review articles become more limited in scope, more specialized. The disturbing phenomenon is that in some disciplines, certainly in chemistry, authors are reluctant to treat even those limited-in-scope reviews exhaustively. There is a trend to preselect the literature, sometimes under the pretext of reducing it to manageable size. The crucial problem with such preselection - as far as numerical data are concerned - is that there is no indication as to whether the material was excluded by design or by a less than thorough literature search. We are equally concerned that most current secondary sources, critical in character as they may be, give scant attention to numerical data.

On the other hand, tertiary sources - handbooks, reference books, and other tabulated and graphical compilations - as they exist today, are comprehensive but, as a rule, uncritical. They usually attempt to cover whole disciplines, thus obviously are superficial in treatment. Since they command a wide market, we believe that their service to advancement of science is at least questionable. Additionally, the change which is taking place in the generation of new and diversified numerical data, and the rate at which this is done, is not reflected in an increased third-level service. The emergence of new tertiary literature sources does not parallel the shift that has occurred in the primary literature.

With the status of current secondary and tertiary services being as briefly stated above, the innovative approach of the *Solubility Data Project* is that its compilation and critical evaluation work involve consolidation and reprocessing services when both activities are based on intellectual and scholarly reworking of information from primary sources. It comprises compact compilation, rationalization and simplification, and the fitting of isolated numerical data into a critically evaluated general framework.

## Foreword

The *Solubility Data Project* has developed a mechanism which involves a number of innovations in exploiting the literature fully, and which contains new elements of a more imaginative approach for transfer of reliable information from primary to secondary/tertiary sources. *The fundamental trend of the Solubility Data Project is toward integration of secondary and tertiary services with the objective of producing in-depth critical analysis and evaluation which are characteristic to secondary services, in a scope as broad as conventional tertiary services.*

Fundamental to the philosophy of the project is the recognition that the basic element of strength is the active participation of career scientists in it. Consolidating primary data, producing a truly critically evaluated set of numerical data, and synthesizing data in a meaningful relationship are demands considered worthy of the efforts of top scientists. Career scientists, who themselves contribute to science by their involvement in active scientific research, are the backbone of the project. The scholarly work is commissioned to recognized authorities, involving a process of careful selection in the best tradition of IUPAC. This selection in turn is the key to the quality of the output. These top experts are expected to view their specific topics dispassionately, paying equal attention to their own contributions and to those of their peers. They digest literature data into a coherent story by weeding out what is wrong from what is believed to be right. To fulfill this task, the evaluator must cover all relevant open literature. No reference is excluded by design and every effort is made to detect every relevant primary source. Poor quality or wrong data are mentioned and explicitly disqualified as such. In fact, it is only when the reliable data are presented alongside the unreliable data that proper justice can be done. The user is bound to have incomparably more confidence in a succinct evaluative commentary and a comprehensive review with a complete bibliography of both good and poor data.

It is the standard practice that any given solute-solvent system consists of two essential parts: (1) critical evaluation and recommended values, and (2) compiled data sheets.

The critical evaluation part gives the following information:

- (i) a verbal text of evaluation which discusses the numerical solubility information appearing in the primary sources located in the literature. The evaluation text concerns primarily the quality of data after consideration of the purity of the materials and their characterization, the experimental method employed and the uncertainties in control of physical parameters, the reproducibility of the data, the agreement of the worker's results on accepted test systems with standard values, and finally, the fitting of data, with suitable statistical tests, to mathematical functions;
- (ii) a set of recommended numerical data. Whenever possible, the set of recommended data includes weighted average and standard deviations, and a set of smoothing equations derived from the experimental data endorsed by the evaluator;
- (iii) whenever relevant a graphical plot of recommended data is included.

The compilation part consists of data sheets of the best experimental data in the primary literature. Generally speaking, such independent data sheets are given only to the best and endorsed data covering the known range of experimental parameters. Data sheets based on primary sources where the data are of a lower precision are given only when no better data are available. Experimental data with a precision poorer than considered acceptable are reproduced in the form of data sheets when they are the only known data for a particular system. Such data are considered to be still suitable for some applications, and their presence in the compilation should alert researchers to areas that need more work.

The typical data sheet carries the following information:

- (i) components - definition of the system - their names, formulas and *Chemical Abstracts* registry numbers;
- (ii) reference to the primary source where the numerical information is reported. In cases when the primary source is a less common periodical or a report document, published though of limited availability, abstract references are also given;
- (iii) experimental variables;
- (iv) identification of the compiler;
- (v) experimental values as they appear in the primary source. Whenever available, the data may be given both in tabular and graphical form. If auxiliary information is available, the experimental data are converted also to SI units by the compiler.

## Foreword

Under the general heading of auxiliary information, the essential experimental details are summarized:

- (vi) experimental method used for the generation of data;
- (vii) type of apparatus and procedure employed;
- (viii) source and purity of materials;
- (ix) estimated error;
- (x) references relevant to the generation of experimental data as cited in the primary source.

This new approach to numerical data presentation has been strongly influenced by the diversity of background of those whom we are supposed to serve. We thus deemed it right to preface the evaluation/compilation sheets in each volume with a detailed discussion of the principles of the accurate determination of relevant solubility data and related thermodynamic information.

Finally, the role of education is more than corollary to the efforts we are seeking. The scientific standards advocated here are necessary to strengthen science and technology, and should be regarded as a major effort in the training and formation of the next generation of scientists and engineers. Specifically, we believe that there is going to be an impact of our project on scientific communication practices. The quality of consolidation adopted by this program offers down-to-earth guidelines, concrete examples which are bound to make primary publication services more responsive than ever before to the needs of users. The self-regulatory message to scientists of 15 years ago to refrain from unnecessary publication has not achieved much. The literature is still cluttered with poor quality articles. The Weinberg Report (in *Reader in Science Information*, Eds. J. Sherrod and A. Hodina, Microcard Editions Books, Indian Head, Inc., 1973, p. 292) states that "admonition to authors to restrain themselves from premature, unnecessary publication can have little effect unless the climate of the entire technical and scholarly community encourages restraint ..." We think that projects of this kind translate the climate into operational terms by exerting pressure on authors to avoid submitting low-grade material. The type of our output, we hope, will encourage attention to quality as authors will increasingly realize that their work will not be suited for permanent retrievability unless it meets the standards adopted in this project. It should help to dispel confusion in the minds of many authors of what represents a permanently useful bit of information of an archival value, and what does not.

If we succeed in that aim, even partially, we have then done our share in protecting the scientific community from unwanted and irrelevant, wrong numerical information.

A. S. Kertes

## PREFACE

Tetraphenylborates -- compounds containing the  $(C_6H_5)_4B^-$  anion, now commonly abbreviated as  $BPh_4^-$ , are a relatively new addition to chemistry, so that published material on their solubilities is, understandably, limited. Furthermore, the paucity of data on the solubility of tetraphenylborates is compounded by the fact that divalent and multivalent cations are not known to form tetraphenylborates, but instead cause the decomposition of the  $BPh_4^-$  ion. A rare exception in this respect seems to be the complex salt of ruthenium o-phenanthroline, for which solubility data are included in this Volume.

The first mention of tetraphenylborates in the literature is believed to be the 1947 report by Wittig and Keicher, describing the synthesis of lithium tetraphenylborate from triphenylboron and phenyllithium (*Naturwissenschaften*, 1947, 34, 216). Soon thereafter, the synthesis of sodium tetraphenylborate was also accomplished in the same laboratory. (In the early literature, the tetraphenylborate ion was called simply "tetraphenylboron", to be superseded temporarily by the term "tetraphenylboride ion"). Both  $LiBPh_4$  and  $NaBPh_4$  are appreciably soluble in water and immediately after their synthesis attracted the attention of chemists as precipitating agents for the potassium ion, which forms a tetraphenylborate that is sparingly soluble in aqueous solutions. The fact that  $KBPh_4$  is by far the least soluble potassium salt in water ( $\approx 1.8 \times 10^{-4}$  mol  $dm^{-3}$  at 298 K) was probably the single most important factor that led to widespread interest in the tetraphenylborate ion and added impetus to early research on tetraphenylborate as an analytical reagent.

Soon it was discovered that rubidium, cesium, thallium(I), silver and a variety of ammonium ions formed insoluble tetraphenylborates in aqueous solution that could serve as a basis for the detection and quantitative determination of these cations. Thus, the early studies of the solubilities of tetraphenylborates were generally incidental to the development of gravimetric and other analytical procedures, where the primary focus was on the sensitivity of analysis, completeness of precipitation and thermal stability of the precipitates. Given this type of emphasis, many of the solubility data were not of the highest precision and accuracy. Furthermore, much of the analytical work, such as the spot tests for the detection of basic nitrogen compounds, was qualitative in nature, leading merely to the estimation of the orders of magnitude of the solubilities. Therefore, no compilations are provided here for published work of this type. On all aspects of the early studies on tetraphenylborates, the reader is referred to the comprehensive 1960 review by Flaschka and Barnard (in *Advances in Analytical Chemistry and Instrumentation*, Reilly, C. N., Ed., Interscience Publishers, Inc. New York. 1960. Vol. I).

In the 1960's and beyond, interest in tetraphenylborates was rekindled for reasons other than analytical: the  $BPh_4^-$  anion acquired the status of a "reference" ion for a variety of physico-chemical purposes. Thus, Fuoss proposed the estimation of limiting conductivities for single ions in nonaqueous solvents based on the assumption that the limiting conductivities of the  $BPh_4^-$  anion and the *n*-butyltrisopentylammonium (in the original, triisooamyl-*n*-butylammonium) cation were equal. Subsequently, we have witnessed the development and application of many analogous assumptions where a thermodynamic property of the  $BPh_4^-$  anion was equated to the corresponding property of the tetraphenylarsonium or the tetraphenylphosphonium cation. Such assumptions have been extensively applied particularly to the transfer free energies between pairs of solvents. Because values of solubility (ion-activity) products in different solvents are required for the calculation of the transfer free energies, the majority of recent data on the solubility of tetraphenylborates derives from studies where the ultimate objective is the evaluation of the transfer free energies.

Unfortunately, also here many of the published results are not of high quality. Many investigators were satisfied with results expressed to only one or two significant digits. Many have failed to specify such crucial experimental conditions as the extent of temperature control and the method of ascertaining saturation.

Tetraphenylborates are susceptible to decomposition by water, oxygen and acids. The decomposition can be easily detected by uv-spectrophotometry in the 260-280 nm range, but may pass unnoticed when a different analytical method is employed for the determination of the tetraphenylborate. This problem must be borne in mind when evaluating literature data.

Frequently, authors have reported the solubility (ion-activity) product, but not the solubility itself. In such cases, the solubility may be estimated if the correction for the activity coefficients is known or can be neglected. Thermodynamic solubility (ion-activity) products are denoted here by the symbol  $K_{SO}^{\circ}$ , while the concentration solubility products are denoted by  $K_{SO}$ . Almost invariably, the solubilities in the original literature were reported in the units of molarity, here converted to the SI equivalent of mol dm<sup>-3</sup>, referring to moles of the solute per dm<sup>3</sup> of the saturated solution. Occasionally, the reported data were in the units of grams of solute per 100 cm<sup>3</sup> of solution, in which case both the original results and the corresponding values in the units of mol dm<sup>-3</sup> were presented in the Volume. Temperatures have been converted to Kelvin. There are very few reliable solubility data on tetraphenylborates as a function of the temperature. Only in the case of KBPh<sub>4</sub> in water was it possible to express such data by means of a smoothing equation and to calculate the standard enthalpy and entropy from it. Names recommended by Chemical Abstracts and registry numbers were used when available. Common names used in the original literature sources were given in parentheses and sometimes retained in the text.

For this Volume, an attempt was made to survey the literature through the first half of 1978. A few later publications were included when they were specifically brought to the Editor's attention. Undoubtedly, there are errors and omissions in the compilations and evaluations and the Editor will be grateful to readers who will bring these to his attention.

The following associates and members of IUPAC Commission on Solubility Data V.8. as well as other reviewers of this Volume are gratefully acknowledged for their valuable suggestions: Abraham, Chan, Chantooni, Clifford, Kertes, Khoo, Kim, Kolthoff, Loening, Lorimer, and Scrosati. Above all, my special thanks is due to Mark Salomon for his active interest and valuable advice throughout all the phases of this project, including a critical review of the manuscript.

Orest Popovych

Brooklyn, New York.

# INTRODUCTION TO THE SOLUBILITY OF SOLIDS IN LIQUIDS

## *Nature of the Project*

The Solubility Data Project (SDP) has as its aim a comprehensive search of the literature for solubilities of gases, liquids, and solids in liquids or solids. Data of suitable precision are compiled on data sheets in a uniform format. The data for each system are evaluated, and where data from different sources agree sufficiently, recommended values are proposed. The evaluation sheets, recommended values, and compiled data sheets are published on consecutive pages.

This series of volumes includes solubilities of solids of all types in liquids of all types.

## *Definitions*

A *mixture* (1,2) describes a gaseous, liquid, or solid phase containing more than one substance, when the substances are all treated in the same way.

A *solution* (1,2) describes a liquid or solid phase containing more than one substance, when for convenience one of the substances, which is called the *solvent* and may itself be a mixture, is treated differently than the other substances, which are called *solutes*. If the sum of the mole fractions of the solutes is small compared to unity, the solution is called a *dilute solution*.

The *solubility* of a substance B is the relative proportion of B (or a substance related chemically to B) in a mixture which is saturated with respect to solid B at a specified temperature and pressure. *Saturated* implies the existence of equilibrium with respect to the processes of dissolution and precipitation; the equilibrium may be stable or metastable. The solubility of a metastable substance is usually greater than that of the corresponding stable substance. (Strictly speaking, it is the activity of the metastable substance that is greater.) Care must be taken to distinguish true metastability from supersaturation, where equilibrium does not exist.

Either point of view, mixture or solution, may be taken in describing solubility. The two points of view find their expression in the quantities used as measures of solubility and in the reference states used for definition of activities and activity coefficients.

The qualifying phrase "substance related chemically to B" requires comment. The composition of the saturated mixture (or solution) can be described in terms of any suitable set of thermodynamic components. Thus, the solubility of a salt hydrate in water is usually given as the relative proportion of anhydrous salt in solution, rather than the relative proportions of hydrated salt and water.

## *Quantities Used as Measures of Solubility*

1. *Mole fraction of substance B,  $x_B$ :*

$$x_B = n_B / \sum_{i=1}^c n_i \quad (1)$$

where  $n_i$  is the amount of substance of substance  $i$ , and  $c$  is the number of distinct substances present (often the number of thermodynamic components in the system). *Mole per cent of B* is  $100 x_B$ .

2. *Mass fraction of substance B,  $w_B$ :*

$$w_B = m'_B / \sum_{i=1}^c m'_i \quad (2)$$

where  $m'_i$  is the mass of substance  $i$ . *Mass per cent of B* is  $100 w_B$ . The equivalent terms weight fraction and weight per cent are not used.

3. *Solute mole (mass) fraction of solute B (3,4):*

$$x_{S,B} = n_B / \sum_{i=1}^{c'} n_i = x_B / \sum_{i=1}^{c'} x_i \quad (3)$$

where the summation is over the solutes only. For the solvent A,  $x_{S,A} = x_A$ . These quantities are called *Jänecke mole (mass) fractions* in many papers.

4. Molality of solute B (1,2) in a solvent A:

$$m_B = n_B/n_A M_A \quad \text{SI base units: mol kg}^{-1} \quad (4)$$

where  $M_A$  is the molar mass of the solvent.

5. Concentration of solute B (1,2) in a solution of volume V:

$$c_B = [B] = n_B/V \quad \text{SI base units: mol m}^{-3} \quad (5)$$

The terms molarity and molar are not used.

Mole and mass fractions are appropriate to either the mixture or the solution points of view. The other quantities are appropriate to the solution point of view only. In addition of these quantities, the following are useful in conversions between concentrations and other quantities.

6. Density:  $\rho = m/V$  SI base units: kg m<sup>-3</sup> (6)

7. Relative density:  $d$ ; the ratio of the density of a mixture to the density of a reference substance under conditions which must be specified for both (1). The symbol  $d_t^t$  will be used for the density of a mixture at  $t^\circ\text{C}$ , 1 atm divided by the density of water at  $t^\circ\text{C}$ , 1 atm.

Other quantities will be defined in the prefaces to individual volumes or on specific data sheets.

#### *Thermodynamics of Solubility*

The principal aims of the Solubility Data Project are the tabulation and evaluation of: (a) solubilities as defined above; (b) the nature of the saturating solid phase. Thermodynamic analysis of solubility phenomena has two aims: (a) to provide a rational basis for the construction of functions to represent solubility data; (b) to enable thermodynamic quantities to be extracted from solubility data. Both these aims are difficult to achieve in many cases because of a lack of experimental or theoretical information concerning activity coefficients. Where thermodynamic quantities can be found, they are not evaluated critically, since this task would involve critical evaluation of a large body of data that is not directly relevant to solubility. The following discussion is an outline of the principal thermodynamic relations encountered in discussions of solubility. For more extensive discussions and references, see books on thermodynamics, e.g., (5-10).

#### *Activity Coefficients (1)*

(a) *Mixtures.* The activity coefficient  $f_B$  of a substance B is given by

$$RT \ln(f_B x_B) = \mu_B - \mu_B^* \quad (7)$$

where  $\mu_B$  is the chemical potential, and  $\mu_B^*$  is the chemical potential of pure B at the same temperature and pressure. For any substance B in the mixture,

$$\lim_{x_B \rightarrow 1} f_B = 1 \quad (8)$$

(b) *Solutions.*

(i) *Solute substance, B.* The molal activity coefficient  $\gamma_B$  is given by

$$RT \ln(\gamma_B m_B) = \mu_B - (\mu_B - RT \ln m_B)^\infty \quad (9)$$

where the superscript  $^\infty$  indicates an infinitely dilute solution. For any solute B,

$$\gamma_B^\infty = 1 \quad (10)$$

Activity coefficients  $y_B$  connected with concentration  $c_B$ , and  $f_{x,B}$  (called the *rational activity coefficient*) connected with mole fraction  $x_B$  are defined in analogous ways. The relations among them are (1,9):

$$\gamma_B = x_A f_{x,B} = V_A^* (1 - \sum_s c_s) y_B \quad (11)$$

or

## Introduction

$$f_{x,B} = (1 + M_A \sum_S m_S) \gamma_B = V_A^* y_B / V_m \quad (12)$$

or

$$y_B = (V_A + M_A \sum_S m_S V_S) \gamma_B / V_A^* = V_m f_{x,B} / V_A^* \quad (13)$$

where the summations are over all solutes,  $V_A^*$  is the molar volume of the pure solvent,  $V_i$  is the partial molar volume of substance  $i$ , and  $V_m$  is the molar volume of the solution.

For an electrolyte solute  $B \equiv C_{v_+} A_{v_-}$ , the molal activity is replaced by (9)

$$\gamma_B m_B = \gamma_{\pm}^{\nu} m_B^{\nu} Q^{\nu} \quad (14)$$

where  $\nu = \nu_+ + \nu_-$ ,  $Q = (\nu_+^{\nu_+} \nu_-^{\nu_-})^{1/\nu}$ , and  $\gamma_{\pm}$  is the mean ionic molal activity coefficient. A similar relation holds for the concentration activity  $\gamma_{CB}$ . For the mol fractional activity,

$$f_{x,B} x_B = \nu_+^{\nu_+} \nu_-^{\nu_-} f_{\pm}^{\nu} x_{\pm}^{\nu} \quad (15)$$

The quantities  $x_+$  and  $x_-$  are the ionic mole fractions (9), which for a single solute are

$$x_+ = \nu_+ x_B / [1 + (\nu - 1) x_B]; \quad x_- = \nu_- x_B / [1 + (\nu - 1) x_B] \quad (16)$$

(ii) Solvent, A:

The osmotic coefficient,  $\phi$ , of a solvent substance A is defined as (1):

$$\phi = (\mu_A^* - \mu_A) / RT M_A \sum_S m_S \quad (17)$$

where  $\mu_A^*$  is the chemical potential of the pure solvent.

The rational osmotic coefficient,  $\phi_x$ , is defined as (1):

$$\phi_x = (\mu_A - \mu_A^*) / RT \ln x_A = \phi M_A \sum_S m_S / \ln(1 + M_A \sum_S m_S) \quad (18)$$

The activity,  $a_A$ , or the activity coefficient  $f_A$  is often used for the solvent rather than the osmotic coefficient. The activity coefficient is defined relative to pure A, just as for a mixture.

### The Liquid Phase

A general thermodynamic differential equation which gives solubility as a function of temperature, pressure and composition can be derived. The approach is that of Kirkwood and Oppenheim (7). Consider a solid mixture containing  $c'$  thermodynamic components  $i$ . The Gibbs-Duhem equation for this mixture is:

$$\sum_{i=1}^{c'} x_i' (S_i' dT - V_i' dp + d\mu_i) = 0 \quad (19)$$

A liquid mixture in equilibrium with this solid phase contains  $c$  thermodynamic components  $i$ , where, usually,  $c > c'$ . The Gibbs-Duhem equation for the liquid mixture is:

$$\sum_{i=1}^{c'} x_i (S_i dT - V_i dp + d\mu_i) + \sum_{i=c'+1}^c x_i (S_i dT - V_i dp + d\mu_i) = 0 \quad (20)$$

Eliminate  $d\mu_i$  by multiplying (19) by  $x_i$  and (20)  $x_i'$ . After some algebra, and use of:

$$d\mu_i = \sum_{j=2}^c G_{ij} dx_j - S_i dT + V_i dp \quad (21)$$

where (7)

$$G_{ij} = (\partial \mu_i / \partial x_j)_{T,P,x_i \neq x_j} \quad (22)$$

it is found that

$$\begin{aligned} & \sum_{i=2}^{c'} \sum_{j=2}^c (x_i' - x_i x_i' / x_i) G_{ij} dx_j - (x_i' / x_i) \sum_{i=c'+1}^c \sum_{j=2}^c x_i G_{ij} dx_j \\ & = \sum_{i=1}^{c'} x_i' (H_i - H_i') dT / T - \sum_{i=1}^{c'} x_i' (V_i - V_i') dp \end{aligned} \quad (23)$$

where

$$H_i - H_i' = T(S_i - S_i') \quad (24)$$

is the enthalpy of transfer of component  $i$  from the solid to the liquid phase, at a given temperature, pressure and composition, and  $H_i$ ,  $S_i$ ,  $V_i$  are the partial molar enthalpy, entropy, and volume of component  $i$ . Several special cases (all with pressure held constant) will be considered. Other cases will appear in individual evaluations.

(a) *Solubility as a function of temperature.*

Consider a binary solid compound  $A_nB$  in a single solvent A. There is no fundamental thermodynamic distinction between a binary compound of A and B which dissociates completely or partially on melting and a solid mixture of A and B; the binary compound can be regarded as a solid mixture of constant composition. Thus, with  $c = 2$ ,  $c' = 1$ ,  $x_A' = n/(n+1)$ ,  $x_B' = 1/(n+1)$ , eqn (23) becomes

$$(1/x_B - n/x_A) \left\{ 1 + \left( \frac{\partial \ln f_B}{\partial \ln x_B} \right)_{T,P} \right\} dx_B = (nH_A + H_B - H_{AB}^*) dT/RT^2 \quad (25)$$

where the mole fractional activity coefficient has been introduced. If the mixture is a non-electrolyte, and the activity coefficients are given by the expression for a simple mixture (6):

$$RT \ln f_B = wx_A^2 \quad (26)$$

then it can be shown that, if  $w$  is independent of temperature, eqn (25) can be integrated (cf. (5), Chap. XXIII, sect. 5). The enthalpy term becomes

$$\begin{aligned} nH_A + H_B - H_{AB}^* &= \Delta H_{AB} + n(H_A - H_A^*) + (H_B - H_B^*) \\ &= \Delta H_{AB} + w(nx_B^2 + x_A^2) \end{aligned} \quad (27)$$

where  $\Delta H_{AB}$  is the enthalpy of melting and dissociation of one mole of pure solid  $A_nB$ , and  $H_A^*$ ,  $H_B^*$  are the molar enthalpies of pure liquid A and B. The differential equation becomes

$$R d \ln \{x_B(1-x_B)^n\} = -\Delta H_{AB} d\left(\frac{1}{T}\right) - w d\left(\frac{x_A^2 + nx_B^2}{T}\right) \quad (28)$$

Integration from  $x_B, T$  to  $x_B = 1/(1+n)$ ,  $T = T^*$ , the melting point of the pure binary compound, gives:

$$\begin{aligned} \ln \{x_B(1-x_B)^n\} &\approx \ln \left\{ \frac{n^n}{(1+n)^{n+1}} \right\} - \left\{ \frac{\Delta H_{AB}^* - T^* \Delta C_p^*}{R} \right\} \left( \frac{1}{T} - \frac{1}{T^*} \right) \\ &+ \frac{\Delta C_p^*}{R} \ln \left( \frac{T}{T^*} \right) - \frac{w}{R} \left\{ \frac{x_A^2 + nx_B^2}{T} - \frac{n}{(n+1)T^*} \right\} \end{aligned} \quad (29)$$

where  $\Delta C_p^*$  is the change in molar heat capacity accompanying fusion plus decomposition of the compound at temperature  $T^*$ , (assumed here to be independent of temperature and composition), and  $\Delta H_{AB}^*$  is the corresponding change in enthalpy at  $T = T^*$ . Equation (29) has the general form

$$\ln \{x_B(1-x_B)^n\} = A_1 + A_2/T + A_3 \ln T + A_4(x_A^2 + nx_B^2)/T \quad (30)$$

If the solid contains only component B,  $n = 0$  in eqn (29) and (30).

If the infinite dilution standard state is used in eqn (25), eqn (26) becomes

$$RT \ln f_{x,B} = w(x_A^2 - 1) \quad (31)$$

and (27) becomes

$$nH_A + H_B - H_{AB} = (nH_A^* + H_B^\infty - H_{AB}^*) + n(H_A - H_A^*) + (H_B - H_B^\infty) = \Delta H_{AB}^\infty + w(nx_B^2 + x_A^2 - 1) \quad (32)$$

where the first term,  $\Delta H_{AB}^\infty$ , is the enthalpy of melting and dissociation of solid compound  $A_nB$  to the infinitely dilute state of solute B in solvent A;  $H_B^\infty$  is the partial molar enthalpy of the solute at infinite dilution. Clearly, the integral of eqn (25) will have the same form as eqn (29), with  $\Delta H_{AB}(T^*)$ ,  $\Delta C_p^\infty(T^*)$  replacing  $\Delta H_{AB}^*$  and  $\Delta C_p^*$  and  $x_A^2 - 1$  replacing  $x_A^2$  in the last term.

## Introduction

If the liquid phase is an aqueous electrolyte solution, and the solid is a salt hydrate, the above treatment needs slight modification. Using rational mean activity coefficients, eqn (25) becomes

$$Rv(1/x_B - n/x_A) \{1 + (\partial \ln f_{\pm} / \partial \ln x_{\pm})_{T,P}\} dx_B / \{1 + (v-1)x_B\} \\ = \{\Delta H_{AB}^{\infty} + n(H_A - H_A^*) + (H_B - H_B^{\infty})\} d(1/T) \quad (33)$$

If the terms involving activity coefficients and partial molar enthalpies are negligible, then integration gives (cf. (11)):

$$\ln \left\{ \frac{x_B^v (1-x_B)^n}{1+(v-1)x_B} \right\}^{n+v} = \ln \left\{ \frac{n^n}{(n+v)^{n+v}} \right\} - \left\{ \frac{\Delta H_{AB}^{\infty} (T^*) - T^* \Delta C_P^*}{R} \right\} \left( \frac{1}{T} - \frac{1}{T^*} \right) + \frac{\Delta C_P^*}{R} \ln(T/T^*) \quad (34)$$

A similar equation (with  $v=2$  and without the heat capacity terms) has been used to fit solubility data for some MOH=H<sub>2</sub>O systems, where M is an alkali metal; the enthalpy values obtained agreed well with known values (11). In many cases, data on activity coefficients (9) and partial molal enthalpies (8,10) in concentrated solution indicate that the terms involving these quantities are not negligible, although they may remain roughly constant along the solubility temperature curve.

The above analysis shows clearly that a rational thermodynamic basis exists for functional representation of solubility-temperature curves in two-component systems, but may be difficult to apply because of lack of experimental or theoretical knowledge of activity coefficients and partial molar enthalpies. Other phenomena which are related ultimately to the stoichiometric activity coefficients and which complicate interpretation include ion pairing, formation of complex ions, and hydrolysis. Similar considerations hold for the variation of solubility with pressure, except that the effects are relatively smaller at the pressures used in many investigations of solubility (5).

### (b) Solubility as a function of composition.

At constant temperature and pressure, the chemical potential of a saturating solid phase is constant:

$$\mu_{A_n B}^* = \mu_{A_n B}(\text{sln}) = n\mu_A + \mu_B \quad (35)$$

$$= (n\mu_A^* + v_+ \mu_+^{\infty} + v_- \mu_-^{\infty}) + nRT \ln f_A x_A \\ + vRT \ln \gamma_{\pm} m_{\pm} Q_{\pm} \quad (36)$$

for a salt hydrate A<sub>n</sub>B which dissociates to water, (A), and a salt, B, one mole of which ionizes to give v<sub>+</sub> cations and v<sub>-</sub> anions in a solution in which other substances (ionized or not) may be present. If the saturated solution is sufficiently dilute, f<sub>A</sub> = x<sub>A</sub> = 1, and the quantity K<sub>S0</sub><sup>0</sup> in

$$\Delta G^{\infty} \equiv (v_+ \mu_+^{\infty} + v_- \mu_-^{\infty} + n\mu_A^* - \mu_{AB}^*) \\ = -RT \ln K_{S0}^0 \\ = -RT \ln Q^v \gamma_{\pm}^v m_+^{v_+} m_-^{v_-} \quad (37)$$

is called the *solubility product* of the salt. (It should be noted that it is not customary to extend this definition to hydrated salts, but there is no reason why they should be excluded.) Values of the solubility product are often given on mole fraction or concentration scales. In dilute solutions, the theoretical behaviour of the activity coefficients as a function of ionic strength is often sufficiently well known that reliable extrapolations to infinite dilution can be made, and values of K<sub>S0</sub><sup>0</sup> can be determined. In more concentrated solutions, the same problems with activity coefficients that were outlined in the section on variation of solubility with temperature still occur. If these complications do not arise, the solubility of a hydrate salt C<sub>v+</sub>A<sub>v-</sub>·nH<sub>2</sub>O in the presence of other solutes is given by eqn (36) as

$$v \ln \{m_B/m_B(0)\} = -v \ln \{\gamma_{\pm}/\gamma_{\pm}(0)\} - n \ln \{a_{H_2O}/a_{H_2O}(0)\} \quad (38)$$

where a<sub>H<sub>2</sub>O</sub> is the activity of water in the saturated solution, m<sub>B</sub> is the molality of the salt in the saturated solution, and (0) indicates absence of other solutes. Similar considerations hold for non-electrolytes.

*The Solid Phase*

The definition of solubility permits the occurrence of a single solid phase which may be a pure anhydrous compound, a salt hydrate, a non-stoichiometric compound, or a solid mixture (or solid solution, or "mixed crystals"), and may be stable or metastable. As well, any number of solid phases consistent with the requirements of the phase rule may be present. Metastable solid phases are of widespread occurrence, and may appear as polymorphic (or allotropic) forms or crystal solvates whose rate of transition to more stable forms is very slow. Surface heterogeneity may also give rise to metastability, either when one solid precipitates on the surface of another, or if the size of the solid particles is sufficiently small that surface effects become important. In either case, the solid is not in stable equilibrium with the solution. The stability of a solid may also be affected by the atmosphere in which the system is equilibrated.

Many of these phenomena require very careful, and often prolonged, equilibration for their investigation and elimination. A very general analytical method, the "wet residues" method of Schreinemakers (12) (see a text on physical chemistry) is usually used to investigate the composition of solid phases in equilibrium with salt solutions. In principle, the same method can be used with systems of other types. Many other techniques for examination of solids, in particular X-ray, optical, and thermal analysis methods, are used in conjunction with chemical analyses (including the wet residues method).

## COMPILATIONS AND EVALUATIONS

The formats for the compilations and critical evaluations have been standardized for all volumes. A brief description of the data sheets has been given in the FOREWORD; additional explanation is given below.

*Guide to the Compilations*

The format used for the compilations is, for the most part, self-explanatory. The details presented below are those which are not found in the FOREWORD or which are not self-evident.

*Components.* Each component is listed according to IUPAC name, formula, and Chemical Abstracts (CA) Registry Number. The formula is given either in terms of the IUPAC or Hill (13) system and the choice of formula is governed by what is usual for most current users: i.e. IUPAC for inorganic compounds, and Hill system for organic compounds. Components are ordered according to:

- (a) saturating components;
- (b) non-saturating components in alphanumerical order;
- (c) solvents in alphanumerical order.

The saturating components are arranged in order according to a 18-column, 2-row periodic table:

Columns 1,2: H, groups IA, IIA;  
 3,12: transition elements (groups IIIB to VIIB, group VIII,  
 groups IB, IIB);  
 13-18: groups IIIA-VIIA, noble gases.

Row 1: Ce to Lu;

Row 2: Th to the end of the known elements, in order of atomic number.

Salt hydrates are generally not considered to be saturating components since most solubilities are expressed in terms of the anhydrous salt. The existence of hydrates or solvates is carefully noted in the texts, and CA Registry Numbers are given where available, usually in the critical evaluation. Mineralogical names are also quoted, along with their CA Registry Numbers, again usually in the critical evaluation.

*Original Measurements.* References are abbreviated in the forms given by *Chemical Abstracts Service Source Index (CASSI)*. Names originally in other than Roman alphabets are given as transliterated by *Chemical Abstracts*.

*Experimental Values.* Data are reported in the units used in the original publication, with the exception that modern names for units and quantities are used; e.g., mass per cent for weight per cent; mol dm<sup>-3</sup> for molar; etc. Both mass and molar values are given. Usually, only one type of value (e.g., mass per cent) is found in the original paper, and the compiler has added the other type of value (e.g., mole per cent) from computer calculations based on 1976 atomic weights (14). Errors in calculations and fitting equations in original papers have been noted and corrected, by computer calculations where necessary.

*Method. Source and Purity of Materials.* Abbreviations used in *Chemical Abstracts* are often used here to save space.

*Estimated Error.* If these data were omitted by the original authors, and if relevant information is available, the compilers have attempted to

estimate errors from the internal consistency of data and type of apparatus used. Methods used by the compilers for estimating and reporting errors are based on the papers by Ku and Eisenhart (15).

*Comments and/or Additional Data.* Many compilations include this section which provides short comments relevant to the general nature of the work or additional experimental and thermodynamic data which are judged by the compiler to be of value to the reader.

*References.* See the above description for Original Measurements.

#### Guide to the Evaluations

The evaluator's task is to check whether the compiled data are correct, to assess the reliability and quality of the data, to estimate errors where necessary, and to recommend "best" values. The evaluation takes the form of a summary in which all the data supplied by the compiler have been critically reviewed. A brief description of the evaluation sheets is given below.

*Components.* See the description for the Compilations.

*Evaluator.* Name and date up to which the literature was checked.

#### Critical Evaluation

(a) *Critical text.* The evaluator produces text evaluating all the published data for each given system. Thus, in this section the evaluator review the merits or shortcomings of the various data. Only published data are considered; even published data can be considered only if the experimental data permit an assessment of reliability.

(b) *Fitting equations.* If the use of a smoothing equation is justifiable, the evaluator may provide an equation representing the solubility as a function of the variables reported on all the compilation sheets.

(c) *Graphical summary.* In addition to (b) above, graphical summaries are often given.

(d) *Recommended values.* Data are *recommended* if the results of at least two independent groups are available and they are in good agreement, and if the evaluator has no doubt as to the adequacy and reliability of the applied experimental and computational procedures. Data are reported as *tentative* if only one set of measurements is available, or if the evaluator considers some aspect of the computational or experimental method as mildly undesirable but estimates that it should cause only minor errors. Data are considered as *doubtful* if the evaluator considers some aspect of the computational or experimental method as undesirable but still considers the data to have some value in those instances where the order of magnitude of the solubility is needed. Data determined by an inadequate method or under ill-defined conditions are *rejected*. However references to these data are included in the evaluation together with a comment by the evaluator as to the reason for their rejection.

(e) *References.* All pertinent references are given here. References to those data which, by virtue of their poor precision, have been rejected and not compiled are also listed in this section.

(f) *Units.* While the original data may be reported in the units used by the investigators, the final recommended values are reported in S.I. units (1,16) when the data can be accurately converted.

## CRITICAL EVALUATION:

The only datum on the solubility of sodium tetraphenylborate (NaBPh<sub>4</sub>) in water which is backed up by detailed and unambiguous information on the experimental conditions involved is that reported by Kirgintsev and Kozitskii (1) as part of their study of the solubility in the acetone-water system (see compilation on the solubility of NaBPh<sub>4</sub> in acetone-water mixtures). At 298.15 K, the solubility reported in the above study was 32.4 (wt./vol.)%, recalculated by the compiler to be 0.947 mol dm<sup>-3</sup>. Another solubility value for NaBPh<sub>4</sub> in water can be found in the chapter by Flaschka and Barnard (2) citing as the source "personal communication" from H. Buechl. It is reported to be approximately 0.88 mol dm<sup>-3</sup>, with the temperature being either 297 for 298 K. The determination was described as "direct analysis", presumably meaning the method of evaporation and weighing. However, as the experimental details related in the review of Flaschka and Barnard (2) are rather sketchy and an original report is in fact unavailable, no compilation sheet is provided for this original datum. In the case of KBPh<sub>4</sub>, the solubility in water increased by about 2% per degree, so that if the same temperature dependence governs the solubility of NaBPh<sub>4</sub>, one could not attribute the difference between 0.947 mol dm<sup>-3</sup> and 0.88 mol dm<sup>-3</sup> to the possible difference of 1 K in the temperature. A third literature value related to the solubility of NaBPh<sub>4</sub> in water is the corresponding solubility product listed as K<sub>sp</sub><sup>o</sup> = 2.14 x 10<sup>-2</sup> (presumably mol<sup>2</sup> dm<sup>-6</sup>) in the book by Clifford (3). Unfortunately, the original source of that value is not given there and taking simply the square root of the K<sub>sp</sub><sup>o</sup> leads to the value 0.146, suggesting that either a large activity correction had been taken into account, or it is based on very poor analytical work. Obviously, no original compilation sheet could be provided for that literature source. Considering that the work of Kirgintsev and Kozitskii (1) was carried out under good temperature control (±0.05°C), with the analysis performed both by the method of evaporation and weighing as well as by precipitation as KBPh<sub>4</sub> and bearing in mind the quality of other results from the same laboratory (see evaluation for KBPh in water), their solubility value can be taken as the tentative value at 298.15 K: 0.947 mol dm<sup>-3</sup>.

<b>AUXILIARY INFORMATION</b>																																																									
<b>METHOD/APPARATUS/PROCEDURE:</b> Evaporating and weighing. Saturated solutions prepared by shaking the suspensions in a constant-temperature bath for 6 hours. Aliquots removed through cotton plugs were evaporated first under an IR lamp and then dried for a week in a vacuum desiccator. Composition of the liquid phase was also checked by precipitation as $\text{KBPh}_4$ . $\text{NaBPh}_4$ recovered from acetone and its aqueous mixtures containing up to 8% water contained the solvent. At higher water contents in the solvent, no crystal solvates were formed.	<b>SOURCE AND PURITY OF MATERIALS:</b> Sodium tetraphenylborate of "analytical grade" obtained from the Apolda Co. (GDR) was purified by recrystallization from acetone-toluene, followed by dissolution in water and extraction with ether. The latter was removed <u>in vacuo</u> . The purity of the salt was no less than 99.6%. Absolute acetone was prepared by treating with $\text{KMnO}_4$ followed by triple fractionation. The final water content was 0.007 vol. %, by Karl Fisher titration.

Y. 11210, U. S. A.  February 1979</p>
<p>CRITICAL EVALUATION:</p> <p>A total of eleven publications dealing with the solubility of potassium tetraphenylborate (<math>\text{KBPh}_4</math>) in aqueous solutions have been reviewed. Nine of them report the solubility directly (1-9), while the remaining two (10, 11) report only the solubility product. Two studies report the solubility as a function of the temperature (7, 8) and only one deals with the variation of the solubility as a function of the temperature, ionic strength and pH (8). In one publication (9), the solubility was reported in a buffer solution, but not in pure water.</p> <p>Three of the data had to be rejected outright (no compilation sheets provided). One was the datum of Raff and Brotz (1), who published an order-of-magnitude value for the solubility as being less than <math>10^{-4}</math> mol <math>\text{dm}^{-3}</math>. The latter was estimated from the point of incipient turbidity observed visually by contacting equal volumes of a solution of <math>\text{KCl}</math> and a <math>0.1</math> mol <math>\text{dm}^{-3}</math> solution of <math>\text{LiBPh}_4</math>. Aside from the fact that the observed solubility corresponds not to pure water, but to a solution containing <math>0.05</math> mol <math>\text{dm}^{-3}</math> <math>\text{LiBPh}_4</math>, the entire determination was aimed at the order of magnitude of the solubility and not its precise value. The latter point has been unfortunately overlooked by subsequent investigators, who attributed more than one significant figure to the datum of Raff and Brotz (1). Another rejected datum was the solubility at <math>292</math> K reported as <math>1.12 \times 10^{-4}</math> mol <math>\text{dm}^{-3}</math> by Levina and Panteleeva (2), where no method was specified. Besides, the above value is very low, as compared to other literature data in that temperature range. Also rejected was the early value of the solubility product reported as <math>5 \times 10^{-9}</math> (presumably in <math>\text{mol}^2 \text{dm}^{-6}</math> units) at <math>290</math> K by Rüdorff and Zannier (10). No experimental details were provided there and the authors later revised the above value themselves (3).</p> <p>The relative validities of the acceptable results must be assessed not so much with respect to the inherent precisions of the analytical methods employed (which are roughly comparable) as with respect to the experimental conditions, such as the time of equilibration and the attention to possible hydrolytic decomposition of the tetraphenylborate ion.</p> <p><u>Solubility at 298 K.</u></p> <p>The data compiled for <math>298</math> K include one determination by electrolytic conductance (3), three determinations by ultraviolet spectrophotometry (5, 6, 9), one by the method of evaporation and weighing (7), and one employing an amperometric titration (8).</p> <p>The conductometric determination by Rüdorff and Zannier (3) from which the solubility is reported as <math>1.82 \times 10^{-4}</math> mol <math>\text{dm}^{-3}</math> is handicapped by the lack of data on the nature of the conductance apparatus employed and the precision of the temperature control as well as insufficient time of equilibration (4 hours). However, even if we assume that the experimental precision was consistent with the reported value, the latter was calculated from erroneous data. The authors used the value of <math>21</math> S <math>\text{cm}^2 \text{mol}^{-1}</math> for the molar conductivity of the tetraphenylborate ion and combined it with the known (unspecified) value for the <math>\lambda^\infty</math> of the potassium ion to calculate the <math>\Lambda^\infty(\text{KBPh}_4)</math>. If the value <math>\lambda^\infty(\text{K}^+) = 73.50</math> S <math>\text{cm}^2 \text{mol}^{-1}</math> was used, the resulting <math>\Lambda^\infty(\text{KBPh}_4)</math> was <math>94.50</math> S <math>\text{cm}^2 \text{mol}^{-1}</math>. However, if one uses the correct value for <math>\lambda^\infty(\text{BPh}_4^-)</math>, which is <math>19.69</math> S <math>\text{cm}^2 \text{mol}^{-1}</math> (12), the correct value for <math>\Lambda^\infty(\text{KBPh}_4)</math> becomes <math>93.19</math> S <math>\text{cm}^2 \text{mol}^{-1}</math>. Presumably the authors calculated the solubility from the measured electrolytic conductivity <math>\kappa</math> and the calculated <math>\Lambda^\infty(\text{KBPh}_4)</math> using the relationship <math>C = 1000 \kappa / \Lambda^\infty</math>. On this basis, the correct solubility from their data would be <math>1.85 \times 10^{-4}</math> mol <math>\text{dm}^{-3}</math>. This value, however, is based on the <u>limiting</u> molar conductivity, which even at that low concentration applies only approximately. No data are available on the variation of the molar conductivity of <math>\text{KBPh}_4</math> with concentration in water, but using the corresponding constants</p>	

<p>COMPONENTS:</p> <p>(1) Potassium tetraphenylborate (1-);  <math>\text{KC}_2\text{H}_2\text{O}_2\text{B}</math>; [3244-41-5]</p> <p>(2) Water; <math>\text{H}_2\text{O}</math>; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of  Chemistry, City University of  New York, Brooklyn College,  Brooklyn, N. Y. 11210, U. S. A.  February 1979</p>
<p>CRITICAL EVALUATION:</p> <p>for the variation of the molar conductivity of <math>\text{NaBPh}_4</math> with concentration (12), it can be estimated that at <math>1.8 \times 10^{-4} \text{ mol dm}^{-3}</math> the molar conductivity of <math>\text{KBPh}_4</math> would be about 92.2. This would raise the calculated solubility further to <math>1.87 \times 10^{-4} \text{ mol dm}^{-3}</math>.</p> <p>In the opinion of this evaluator, the best method for determining tetraphenylborate concentration is ultraviolet spectrophotometry, as the spectra are very sensitive to decomposition, so that appreciable changes in the shape of the spectral bands and particularly in the ratio of the heights of the 266-nm and 274-nm peaks occur long before any yellow or brown color betrays the presence of decomposition. Thus, decomposition in the course of solubility determinations can be detected when UV-spectrophotometry is the analytical method employed, which is not true of the other analytical methods cited here.</p> <p>Of the two solubility determinations in pure water by the method of uv-spectrophotometry, that by Popovych and Friedman (6) was carried out under more reliable experimental conditions, namely a temperature control to <math>\pm 0.01^\circ\text{C}</math> in the bath from which water was circulated and an equilibration period of two weeks. The reported value is <math>1.74 \times 10^{-4} \text{ mol dm}^{-3}</math> with a relative precision of <math>\pm 1\%</math>. The second uv determination, by Pflaum and Howick (5), reports no information on the temperature control and the length of equilibration. Its further shortcoming is that the authors used the peak molar absorption coefficients <math>\epsilon_{\text{max}}</math> determined in acetonitrile to analyze aqueous solutions. The acetonitrile <math>\epsilon_{\text{max}}</math> values were <math>3.225 \times 10^3</math> and <math>2.110 \times 10^3</math> at 266 and 274 nm, respectively. For aqueous solutions, Popovych and Friedman (6) report the molar absorption coefficients as <math>3.25 \times 10^3</math> and <math>2.06 \times 10^3</math> at 266 and 274 nm, respectively (all molar absorption coefficients are in the units of <math>\text{dm}^3 (\text{cm mol})^{-1}</math>). Nevertheless, the solubility reported by Pflaum and Howick (5), <math>1.78 \times 10^{-4} \text{ mol dm}^{-3}</math>, agrees with the Popovych and Friedman (6) value, within experimental error. This agreement may be due to certain compensating errors and other mitigating factors. Thus, the solubility of <math>\text{KBPh}_4</math> in the temperature range of 293-298 K varies only by <math>0.04 \times 10^{-4} \text{ mol dm}^{-3}</math> per degree (7). Therefore, a temperature control to only <math>\pm 0.5^\circ\text{C}</math> would suffice to keep the error within the limits of precision imposed by the analytical method (<math>\pm 1\%</math> relative). The <math>\epsilon_{\text{max}}</math> value for the <math>\text{BPh}_4^-</math> anion used by Pflaum and Howick (5) in their calculation of the solubility was 2.5% too high at 274 nm and 1% too low at 266 nm. If the solubility value was determined as the average from the two wavelengths, what we may be seeing here is a compensation of errors.</p> <p>In the uv-determination by McClure and Rechnitz (9), the solubility of <math>\text{KBPh}_4</math> was not measured in pure water, but in a buffer solution consisting of <math>0.1 \text{ mol dm}^{-3}</math> tris(hydroxymethyl)aminomethane and <math>0.01 \text{ mol dm}^{-3}</math> acetic acid adjusted to pH 5.1 with <math>\text{HClO}_4</math>. Thus, the solubility value of <math>2.3 \times 10^{-4} \text{ mol dm}^{-3}</math> reported by them is not comparable with the results at zero ionic strength. However, it may be compared with Siska's (8) data obtained at an ionic strength of <math>0.1 \text{ mol dm}^{-3}</math>, which we discuss later.</p> <p>In excellent agreement with the uv-determined solubilities reported for pure water is the value obtained by evaporation of a saturated solution and weighing of the residue (7). Here, two solubility values are reported at 298 K, one resulting from a continuous equilibration at the stated temperature for 12 hours: <math>1.74 \times 10^{-4} \text{ mol dm}^{-3}</math> (<math>1.75 \times 10^{-4} \text{ mol dm}^{-3}</math> in the original, due to an error in converting from wt %) and the other, resulting from a preliminary equilibration at <math>40^\circ\text{C}</math> for 6 hours, followed by 12 hours at <math>25^\circ\text{C}</math>: <math>1.79 \times 10^{-4} \text{ mol dm}^{-3}</math>. This study is characterized by good temperature control (<math>\pm 0.05^\circ\text{C}</math>) and a reasonable time of equilibration.</p>

Y. 11210, U. S. A.  February 1979</p>
--	--

## CRITICAL EVALUATION:

Recommended Values at 298.15 K

Combining the average value reported by Kozitskii (7),  $1.76 \times 10^{-4}$  mol dm<sup>-3</sup>, by Popovych and Friedman (6),  $1.74 \times 10^{-4}$  mol dm<sup>-3</sup>, and by Pflaum and Howick (5),  $1.78 \times 10^{-4}$  mol dm<sup>-3</sup>, we obtain the overall average from three studies by two different methods as:

$$\text{Solubility} = (1.76 \pm 0.02) \times 10^{-4} \text{ mol dm}^{-3}$$

The absolute error derives from the relative precision of a uv-determination of the tetraphenylborate concentration, which is  $\pm 1\%$  (6).

The solubility product can be calculated as  $K_{s0}^{\circ} = (C_{y_{\pm}})^2$ , where the mean molar ionic activity coefficient  $y_{\pm}^2$  is estimated from the Debye-Hückel limiting law:  $\log y_{\pm}^2 = -1.18(1.76 \times 10^{-4})^{1/2}$ . This yields  $y_{\pm}^2 = 0.969$  and

$$K_{s0}^{\circ} = (3.00 \pm 0.04) \times 10^{-8} \text{ mol}^2 \text{ dm}^{-6}$$

The absolute error in the  $K_{s0}^{\circ}$  was calculated assuming the 1% error in C as its only source.

Solubility at Other Temperatures

At 293 K, the solubility can be found in two literature sources (4,7), reported directly and in another source where it is reported in the form of the solubility product (11). Closest agreement exists between the value published by Kozitskii (7),  $1.56 \times 10^{-4}$  mol dm<sup>-3</sup>, which was determined by evaporation and weighing, and the radiometrically determined value of  $1.48 \times 10^{-4}$  mol dm<sup>-3</sup> reported by Geilman and Gebauhr (4). Unfortunately, even these two values are not quite close enough to merit averaging for a recommended value. Considering that Kozitskii specified an equilibration time of 24 hours and that his solubility at 298 K is equal to the recommended value at that temperature, this evaluator chooses  $1.56 \times 10^{-4}$  mol dm<sup>-3</sup> as the tentative value for the solubility at 293 K. Geilman and Gebauhr (4), on the other hand, did not specify the time of equilibration.

The other solubility values reported for 293 K appear to be too low. From a potentiometric titration, Havir (11) reports a solubility product of  $1.6 \times 10^{-8}$  (presumably in mol<sup>2</sup> dm<sup>-6</sup> units), from which the solubility taken simply as the square root would be  $1.3 \times 10^{-4}$  mol dm<sup>-3</sup>. No equilibration time was specified here, but considering that the solubility of AgBPh<sub>4</sub> reported in the same article was determined after only 4 hours of equilibration, it is likely that a similar time was used for KBPh<sub>4</sub>. It should be noted that the intention of the author in this case was to demonstrate the concentration limit to which a potentiometric titration of the BPh<sub>4</sub><sup>-</sup> ion was feasible and that the determination of the solubility of KBPh<sub>4</sub> was incidental. Similarly, Siska's (8) value of  $1.25 \times 10^{-4}$  mol dm<sup>-3</sup>, which was determined after only 3 hours of equilibration, must be too low due to absence of saturation.

Both Siska (8) and Kozitskii (7) reported the solubility at several temperatures. Siska also showed tables of the solubility as a function of ionic strength and the pH. Most of his values were determined at an ionic strength of 0.1 mol dm<sup>-3</sup> and are therefore not directly comparable with other literature data. However, judging from the one datum given for zero ionic strength at 293 K ( $1.25 \times 10^{-4}$  mol dm<sup>-3</sup>) and from the fact that Siska's data at other temperatures at 0.1 ionic strength are of approximately the same magnitude as other literature data at zero ionic strength, it seems that all the results in this most comprehensive study of the solubility of KBPh<sub>4</sub> in aqueous solutions are too low due to

<p>COMPONENTS:</p> <p>(1) Potassium tetraphenylborate (1-);  <math>KC_{24}H_{20}B</math>; [3244-41-5]</p> <p>(2) Water; <math>H_2O</math>; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of  Chemistry, City University of  New York, Brooklyn College,  Brooklyn, N. Y. 11210, U. S. A.  February 1979</p>
--	--

## CRITICAL EVALUATION:

undersaturation. This conclusion seems also to be corroborated by the fact that the solubility of  $KBPh_4$  in a  $0.1 \text{ mol dm}^{-3}$  buffer solution reported by McClure and Rechnitz (9) at 298 K, ( $2.3 \times 10^{-4} \text{ mol dm}^{-3}$ ) is higher than the solubility reported by Siska at 303 K ( $2.13 \times 10^{-4} \text{ mol dm}^{-3}$ ). Consequently, we are again limited to stating as tentative values those solubilities that were reported by Kozitskii (7) at other temperatures as well. Below we tabulate these solubilities as well as the solubility products derived from them using mean molar activity coefficients  $\gamma_{\pm}$  estimated from the Debye-Hückel limiting law. It should be noted that in the concentration range involved, the use of a Debye-Hückel expression with ion-sized parameters would result in a change of about one part per thousand only.

Solubility at Different Temperatures (8)

T/K	$10^4 C/\text{mol dm}^{-3}$	$10^8 K_{SO}^{\circ}/\text{mol}^2 \text{ dm}^{-6*}$	A (Debye-Hückel)

298.15	1.76	3.00	0.509
323.15	3.71	13.1	0.537

\* Calculated by the evaluator as  $K_{SO}^{\circ} = C^2 \gamma_{\pm}^2$ , where  $\log \gamma_{\pm}^2 = -2A(C)^{\frac{1}{2}}$  and the units of A are  $\text{mol}^{-1/2} \text{ dm}^{3/2}$ .

A plot of  $\log K_{SO}^{\circ}$  vs.  $T^{-1}$  is linear only in the range of 293-323 K, for which the smoothing equation obtained by the method of least squares is:  $\log K_{SO}^{\circ} = -2387/(T/K) + 0.501$ , with  $\sigma_y = 0.013$  (absolute) and a correlation coefficient of -0.999. The highly tentative values for the thermodynamic constants calculated from the above slope and intercept are:

$$\Delta H^{\circ} + 45.7 \pm 1.8 \text{ kJ mol}^{-1} \text{ and } \Delta S^{\circ} = 9.6 \pm 6.1 \text{ JK}^{-1} \text{ mol}^{-1}.$$

All four points can be described by the equation:

$$\log K_{SO}^{\circ} = 30.97 - 2.121 - 10^4/(T/K) + 2.903 \times 10^6/(T/K)^2 \text{ with } \sigma_y = 0.006 \text{ (abs.)}.$$

<b>COMPONENTS:</b>  (1) Potassium tetraphenylborate (1-); $\text{KC}_2\text{H}_2\text{O}_2\text{B}$ ; [3244-41-5]  (2) Water; $\text{H}_2\text{O}$ ; [7732-18-5]	<b>ORIGINAL MEASUREMENTS:</b>  Rüdorff, W.; Zannier, H.  <i>Z. Naturforsch.</i> <u>1953</u> , <i>8b</i> , 611-2.
<b>VARIABLES:</b>  One temperature: 25°C	<b>PREPARED BY:</b>  Orest Popovych
<b>EXPERIMENTAL VALUES:</b> The solubility of potassium tetraphenylborate ( $\text{KBPh}_4$ ) was reported as $1.82 \times 10^{-4} \text{ mol dm}^{-3}$ and the solubility product, $K_{\text{SO}}$ , as $3.3 \times 10^{-8} \text{ mol}^2 \text{ dm}^{-6}$ .  The authors determined the limiting molar conductivity of sodium tetraphenylborate to be $71 \text{ S cm}^2 \text{ mol}^{-1}$ , from which they derived the value of $21 \text{ S cm}^2 \text{ mol}^{-1}$ for the $\lambda^\infty$ of the tetraphenylborate anion. Combining the latter with the known (unspecified) value for the $\lambda^\infty(\text{K}^+)$ , the authors calculated the solubility from the conductance of the saturated solution of potassium tetraphenylborate, presumably using the relationship: $C = 1000 \kappa / \Lambda^\infty$ , where $C$ is the solubility and $\kappa$ , the electrolytic conductivity of the solution corrected for solvent conductance (magnitude not specified). The calculation method, however, was not explained in the article.  The present results were reported as an improvement over the previously published by the same author (1) value of $K_{\text{SO}} = 5 \times 10^{-9}$ (presumably in units of $\text{mol}^2 \text{ dm}^{-6}$ ), which was also derived from conductance data.	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> Electrolytic conductance on unspecified apparatus. Temperature controlled, but within unspecified limits. Saturated solutions of $\text{KBPh}_4$ were prepared by bubbling nitrogen through its suspensions in conductivity water for 4 hours.	<b>SOURCE AND PURITY OF MATERIALS:</b> $\text{NaBPh}_4$ from the Heyl Co. of Hildesheim, Germany, was purified in the absence of air by just dissolving it in chloroform-acetone mixture and precipitating with petroleum ether. After repeated treatment, it was recrystallized under $\text{N}_2$ from chloroform and vacuum dried. $\text{KBPh}_4$ was recrystallized from acetone-ethyl acetate.  <b>ESTIMATED ERROR:</b>  Nothing specified.  <b>REFERENCES:</b>  Rüdorff, W.; Zannier, H.  <i>Angew. Chem.</i> <u>1952</u> , <i>64</i> , 613.

COMMENTS AND/OR ADDITIONAL DATA:

Keeping the ionic strength constant at  $0.1 \text{ mol dm}^{-3}$  with sodium sulfate, the following solubilities  $C$  were obtained as a function of the temperature:

$t/^\circ C$	$10^4 C/\text{mol dm}^{-3}$
10	1.19
20	1.50
30	2.13
40	2.45
45	2.98

Keeping the ionic strength constant at  $0.1 \text{ mol dm}^{-3}$ , with sodium sulfate, the following solubilities  $C$  were obtained as a function of the pH varied by means of acetic acid and sodium hydroxide at  $20 \pm 1^\circ C$ :

pH	$10^4 C/\text{mol dm}^{-3}$	pH	$10^4 C/\text{mol dm}^{-3}$
1.3	0.30	11.5	1.40
1.8	0.94	11.6	1.40
2.8	1.54	11.6	1.42
3.0	1.42	11.7	1.50
4.6	1.48	3.7	1.42
5.7	1.44	3.9	1.40
6.6	1.45		
6.9	1.44		
7.8	1.42		
8.8	1.42		
10.2	1.56		
10.4	1.44		
10.6	1.50		
11.2	1.46		

The authors report at an ionic strength of 0.1 and the pH range of 2.8-11.7, the following solubility value for potassium tetraphenylborate in aqueous solution:  
 $C = 1.45 \times 10^{-4} \text{ mol dm}^{-3}$ .  
The error in the above value was stated as 0.046 ( $10^{-4} \text{ mol dm}^{-3}$ ), presumably referring to the precision.

<b>COMPONENTS:</b> (1) Potassium tetraphenylborate (1-); $\text{KC}_2\text{H}_4\text{B}$ ; [3244-41-5] (2) Tris(hydroxymethyl)aminomethane; $\text{C}_4\text{H}_{11}\text{NO}_3$ ; [77-86-1] (3) Acetic acid; $\text{C}_2\text{H}_4\text{O}_2$ ; [64-19-7] (4) Water; $\text{H}_2\text{O}$ ; [7732-18-5]	<b>ORIGINAL MEASUREMENTS:</b> McClure, J. <b>VARIABLES:</b>  One temperature: 20°C	<b>PREPARED BY:</b>  Orest Popovych
<b>EXPERIMENTAL VALUES:</b>  <p>The solubility product of potassium tetraphenylborate (<math>\text{KBPh}_4</math>) in water is reported to be:  <math>K_{\text{SO}} = 1.6 \times 10^{-8}</math> presumably in <math>\text{mol}^2 \text{dm}^{-6}</math> units (compiler). The corresponding solubility calculated as <math>(K_{\text{SO}})^{\frac{1}{2}}</math> is:  <math>C = 1.3 \times 10^{-4} \text{ mol dm}^{-3}</math> (compiler).</p>	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> Potentiometric titration of the tetraphenylborate ion in saturated $\text{KBPh}_4$ solutions with $\text{AgNO}_3$ using a freshly plated silver indicator electrode and a saturated calomel reference electrode dipping in a solution of 10% $\text{NaNO}_3$ . The salt bridge was a 2% Agar-Agar solution in a 10% $\text{NaNO}_3$ solution. An Ionoskop potentiometer was used.	<b>SOURCE AND PURITY OF MATERIALS:</b> $\text{NaBPh}_4$ was obtained from the Heyl Co. (Berlin), but the method of preparation and purification of the potassium salt was not specified.  <b>ESTIMATED ERROR:</b>  Nothing specified.  <b>REFERENCES:</b>

<b>COMPONENTS:</b> (1) Potassium tetraphenylborate (1-); $KC_{24}H_{20}B$ ; [3244-41-5] (2) 2-Propanone (acetone); $C_3H_6O$ ; [67-64-1] (3) Water; $H_2O$ ; [7732-18-5]	<b>EVALUATOR:</b> Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979
<b>CRITICAL EVALUATION:</b> <p>The solubility of potassium tetraphenylborate (<math>KBPh_4</math>) in acetone-water mixtures was determined at 301 K by Scott et al. (1) and at 298.15 K by Kirgintsev and Kozitskii (2). This difference in the temperature and, to a smaller degree, the fact that the acetone in the first study was of reagent grade and may have contained up to 0.5% water preclude a comparison of the two sets of data. Only for pure acetone was it possible to make a comparison between the results obtained from the above two studies, but the agreement was very poor. Thus, according to Scott et al. (1) the solubility in acetone at 301 K was <math>0.117 \text{ mol dm}^{-3}</math>, while a smoothing equation based on the data of Kirgintsev and Kozitskii (2, 3) predicted a solubility of <math>0.165 \text{ mol dm}^{-3}</math> at 301 K (see evaluation for <math>KBPh_4</math> in acetone). Of course, it is impossible to tell whether or not the two sets of data would similarly disagree at other solvent compositions, since data for the solubility as a function of the temperature are not available for acetone-water mixtures. At this time, the solubilities reported for acetone-water mixtures by Kirgintsev and Kozitskii (2) should be regarded as the <u>tentative values at 298.15 K</u>. They were obtained under good temperature control (<math>\pm 0.05^\circ\text{C}</math>), but the equilibration time of 6 hours may have been insufficient for complete saturation.</p> <b>REFERENCES:</b> <ol style="list-style-type: none"><li>1. <b>AUXILIARY INFORMATION</b>																																																			
<b>METHOD/APPARATUS/PROCEDURE:</b> Evaporation and weighing. Saturated solutions were prepared by shaking the suspensions in a constant-temperature bath for 6 hours. Aliquots were removed through cotton plugs, weighed and the solvent removed by evaporation first under an IR lamp and then by oven-drying to constant weight at 105°C. The solid phase contained no solvent when recrystallized from acetone or acetone-water mixtures.	<b>SOURCE AND PURITY OF MATERIALS:</b> $NaBPh_4$ ("analytical grade" from the Apolda Co., GDR) was purified by recrystallization from acetone-toluene, followed by dissolution in water, extraction with ether, and removal of the latter <u>in vacuo</u> . The purity of the final $NaBPh_4$ was no less than 99.6%. $KBPh_4$ was prepared by metathesis of $NaBPh_4$ with KCl and purified by double recrystallization from 20% water 80% acetone (probably by vol.). The acetone was slowly evaporated and the precipitate kept for a long time under high vacuum. Acetone was treated with $KMnO_4$ followed by triple fractionation. Final water content was 0.007 vol. % by Karl Fisher titration.

<b>AUXILIARY INFORMATION</b>																											
<b>METHOD/APPARATUS/PROCEDURE:</b> Ultraviolet spectrophotometry using a Cary Model 14 spectrophotometer. Saturated solutions were prepared by shaking suspensions of $\text{KBPh}_4$ in water-jacketed flasks. A solution was considered saturated when successive weekly analyses agreed to about 1%. This required about 2 weeks of equilibration for solutions without added $\text{LiCl}$ and one month for solutions with added $\text{LiCl}$ . Saturated solutions were filtered and analyzed spectrophotometrically using absorption coefficients characteristic of each solvent. All work was carried out in deaerated containers and solvents.	<b>SOURCE AND PURITY OF MATERIALS:</b> $\text{KBPh}_4$ was prepared from $\text{NaBPh}_4$ (Fisher, 99.7%) by metathesis with $\text{KCl}$ ; it was recrystallized three times from 3:1 acetone-water and dried <u>in vacuo</u> at 80°C. Baker analyzed $\text{LiCl}$ was doubly recrystallized from conductivity water and dried for 48 hours at 110°C. It was stored and transferred in a dry box. USP 95% ethanol was doubly distilled. USP absolute ethanol was refluxed																										
<b>COMMENTS:</b> The results reported in this study can be considered as <u>tentative values</u> .	<b>ESTIMATED ERROR: (For the solubility)</b> Precision $\pm 1\%$ Accuracy $\pm 3\%$ (authors) Temperature: $\pm 0.01^\circ\text{C}$ .  <b>REFERENCES:</b>

COMMENTS AND/OR ADDITIONAL DATA																																																	
<p>EXPERIMENTAL VALUES:</p> <p>The authors determined the mean molar activity coefficients of potassium tetrphenylborate (<math>KBPh_4</math>) in ethanol-water mixtures from the variation of solubility as a function of the ionic strength varied by means of LiCl. The following equations were used:</p> $\log \frac{\alpha_I C_I}{\alpha_o C_o} = \log y_{\pm, o} - \log y_{\pm, I} \quad \text{and} \quad -\log y_{\pm, I} = A_1 I^{1/2} + A_2 I + A_3 I^{3/2} + \dots$ <p>where <math>\alpha</math>'s are the degrees of ionic association, <math>y_{\pm}</math> is the mean molar activity coefficient (<math>f_{\pm}</math> in the original), and the subscripts <math>o</math> and <math>I</math> denote pure solvent and ionic strength <math>I</math> as determined by the sum of LiCl and <math>KBPh_4</math>. At any ionic strength <math>I</math>, the activity coefficient can be calculated from the known A-coefficients. Values of <math>\alpha</math> were calculated from the association constant <math>K_A</math> (1) using the same equation as in the compilation for <math>KBPh_4</math> in methanol (2). <math>C_o</math> is the solubility in the pure solvent.</p> <table border="1" data-bbox="215 866 1196 1128"> <thead> <tr> <th>Mass% ethanol in water</th> <th><math>\alpha_o</math></th> <th><math>y_{\pm, o}</math></th> <th><math>A_1</math></th> <th><math>A_2</math></th> <th><math>K_{SO}^o = (C_o \alpha_o y_{\pm, o})^2,</math> mol<sup>2</sup> dm<sup>-6</sup> (compiler)</th> </tr> </thead> <tbody> <tr> <td>100.0</td> <td>0.949</td> <td>0.849</td> <td>3.90</td> <td>-7.55</td> <td><math>1.65 \times 10^{-7}</math></td> </tr> <tr> <td>78.1</td> <td>0.986</td> <td>0.819</td> <td>2.25</td> <td>-3.47</td> <td><math>3.61 \times 10^{-6}</math></td> </tr> <tr> <td>60.6</td> <td>0.998</td> <td>-----</td> <td>1.30</td> <td>-3.11</td> <td><math>7.71 \times 10^{-6}</math></td> </tr> <tr> <td>38.4</td> <td>1.000</td> <td>-----</td> <td>0.749</td> <td>-0.820</td> <td><math>1.58 \times 10^{-6}</math></td> </tr> <tr> <td>30.0*</td> <td>1.000</td> <td>0.958</td> <td>-----</td> <td>-----</td> <td><math>4.12 \times 10^{-7}</math></td> </tr> <tr> <td>20.0*</td> <td>1.000</td> <td>0.972</td> <td>-----</td> <td>-----</td> <td><math>1.09 \times 10^{-7}</math></td> </tr> <tr> <td>10.0*</td> <td>1.000</td> <td>0.981</td> <td>-----</td> <td>-----</td> <td><math>4.66 \times 10^{-8}</math></td> </tr> </tbody> </table> <p>*Activity coefficients calculated from the Debye-Hückel limiting law.</p>		Mass% ethanol in water	$\alpha_o$	$y_{\pm, o}$	$A_1$	$A_2$	$K_{SO}^o = (C_o \alpha_o y_{\pm, o})^2,$ mol <sup>2</sup> dm <sup>-6</sup> (compiler)	100.0	0.949	0.849	3.90	-7.55	$1.65 \times 10^{-7}$	78.1	0.986	0.819	2.25	-3.47	$3.61 \times 10^{-6}$	60.6	0.998	-----	1.30	-3.11	$7.71 \times 10^{-6}$	38.4	1.000	-----	0.749	-0.820	$1.58 \times 10^{-6}$	30.0*	1.000	0.958	-----	-----	$4.12 \times 10^{-7}$	20.0*	1.000	0.972	-----	-----	$1.09 \times 10^{-7}$	10.0*	1.000	0.981	-----	-----	$4.66 \times 10^{-8}$

COMMENTS AND/OR ADDITIONAL DATA

## EXPERIMENTAL VALUES:

From the variation of the solubility of KBPh<sub>4</sub> as a function of ionic strength varied by means of LiCl, the authors determined the mean ionic activity coefficients of KBPh<sub>4</sub> in the methanol-water mixtures using the following equations:

$$\log C_I/C_O = \log y_{\pm,o} - \log y_{\pm,I} \quad \text{and} \quad -\log y_{\pm,I} = A_1 I^{1/2} + A_2 I + A_3 I^{3/2} + \dots$$

where  $y_{\pm}$  is the mean molar activity coefficient ( $f_{\pm}$  in the original) and the subscripts  $o$  and  $I$  denote solutions without and with added LiCl. Complete dissociation was assumed for all methanol-water mixtures, since KBPh<sub>4</sub> is practically unassociated even in pure methanol (1). At any ionic strength  $I$  (in mol dm<sup>-3</sup>), the solubility  $C_I$  and the activity coefficient can be calculated from the A-coefficients characteristic of the methanol-water mixture, which are tabulated:

Mass % methanol in water	$y_{\pm,o}$	$A_1$	$A_2$	$A_3$	$A_4$	$K_{S0}^{\circ}/\text{mol}^2 \text{ dm}^{-6*}$
89.4	0.882 ± 0.032	1.38	-2.04	1.28	-0.343	(3.84 ± 0.20) x 10 <sup>-6</sup>

<b>AUXILIARY INFORMATION</b>																
<b>METHOD/APPARATUS/PROCEDURE:</b> Saturated solutions were prepared by shaking for 3-4 h followed by equilibration in a thermostat. Filtered, weighed aliquots, after proper dilution with water, were analyzed by uv-spectrophotometry using a Beckman DU 2400 spectrophotometer. The shaking followed by thermostating was repeated at 3-4 day intervals until constant absorption was obtained, which required 2-4 weeks.	<b>SOURCE AND PURITY OF MATERIALS:</b> Urea was purified by a literature method (1). $KBPh_4$ was prepared and purified as described by Popovych and Friedman (2) (see compilation for $KBPh_4$ in water).															
	<b>ESTIMATED ERROR:</b> Temperature: $\pm 0.1^{\circ}C$ Precision in solubility: $\pm 2\%$															
	<b>REFERENCES:</b> (1) Kundu, K. K.; Majumdar, K. <i>J. Chem. Soc. Faraday Trans. 1</i> <u>1973</u> , 69, 807. (2) Popovych, O.; Friedman, R. M. <i>J. Phys. Chem.</i> <u>1966</u> , 70, 1671.															

<p>COMPONENTS:</p> <p>(1) Potassium tetraphenylborate (1-); <math>KC_2H_4B</math>; [3244-41-5]</p> <p>(2) Acetonitrile; <math>C_2H_3N</math>; [75-05-8]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979</p>
<p>CRITICAL EVALUATION:</p> <p>The solubility of potassium tetraphenylborate (<math>KBPh_4</math>) in acetonitrile was reported as such by Kolthoff and Chantooni (1) as well as by Popovych et al. (2). The solubility products of <math>KBPh_4</math> in acetonitrile were reported in the above two studies and also in the two articles by Alexander and Parker (3, 4). All determinations were at 298 K.</p> <p>Excellent agreement exists between the solubility value obtained by Kolthoff and Chantooni (1) from evaporation and weighing, <math>C = 5.40 \times 10^{-2} \text{ mol dm}^{-3}</math> and the value <math>C = 5.33 \times 10^{-2} \text{ mol dm}^{-3}</math> determined by UV-spectrophotometry by Popovych et al. (2). The latter study was carried out under temperature control to <math>0.01^\circ\text{C}</math> in the constant-temperature bath from which water was circulated through jacketed flasks containing the suspensions. Saturation was ascertained by successive analyses days apart until the solubilities agreed to 1% or better. Unfortunately, no experimental details are available in the Kolthoff and Chantooni (1) article as far as the temperature control and saturation attainment is concerned. Nevertheless, if we accept the number of significant figures retained in the result, it is possible to average the values <math>5.33 \times 10^{-2} \text{ mol dm}^{-3}</math> and <math>5.40 \times 10^{-2} \text{ mol dm}^{-3}</math> to arrive at the recommended value for the solubility of <math>KBPh_4</math> in acetonitrile at 298 K: <math>(5.36 \pm 0.05) \times 10^{-2} \text{ mol dm}^{-3}</math>. The indicated precision is that governing the UV-analysis for the <math>BPh_4^-</math> concentration. There are no data on the precision of the analysis by the method of evaporation and weighing.</p> <p>Alexander and Parker report the formal (concentration) solubility product of <math>KBPh_4</math> in acetonitrile as <math>pK_{s0} = 2.7</math> (3) and 2.4 (4) (in volume units) in the two successive studies. Because these are concentration products, the values of the corresponding solubilities can be calculated from them simply as <math>(K_{s0})^{1/2}</math>. When <math>pK_{s0} = 2.7</math>, the solubility is <math>4.5 \times 10^{-2} \text{ mol dm}^{-3}</math>. The solubility corresponding to the <math>pK_{s0} = 2.4</math> is <math>6.3 \times 10^{-2} \text{ mol dm}^{-3}</math>. However, it should be noted that in the second study the authors estimate a precision of <math>\pm 0.2</math> pK units, which means that the solubility derived from it could range from <math>5 \times 10^{-2}</math> to <math>8 \times 10^{-2} \text{ mol dm}^{-3}</math>. Clearly, these results cannot be compared in precision with the recommended values stated above. While in the case of solubility of <math>KBPh_4</math> in acetonitrile it is possible to recommend a value, this is unfortunately not so in the case of the thermodynamic solubility product. The latter was estimated both by Kolthoff and Chantooni (1) as well as by Popovych et al. (2) using calculated activity coefficients and at the concentration involved the differences in the activity corrections can be appreciable. By employing an unspecified form of the Guggenheim equation, Kolthoff and Chantooni calculated a <math>pK_{s0}^\circ = 3.2</math> (<math>K_{s0}^\circ</math> units are <math>\text{mol}^2 \text{ dm}^{-6}</math> in this evaluation). Popovych et al. (2) by using a Debye-Hückel equation shown on the compilation sheet obtained for the mean ionic activity coefficient <math>\gamma_{\pm}^2 = 0.298</math>, from which <math>K_{s0}^\circ = 8.47 \times 10^{-4} \text{ mol}^2 \text{ dm}^{-6}</math> and the <math>pK_{s0}^\circ = 3.07</math>. The above activity coefficient was calculated using ion-size parameters <math>\bar{a} = 0.3 \text{ nm}</math> for the <math>K^+</math> ion and <math>\bar{a} = 0.5 \text{ nm}</math> for the <math>BPh_4^-</math> ion. The latter, however, may be too small. For example, Kolthoff and Chantooni (5) used an ion-size parameter of <math>1.2 \text{ nm}</math> for the <math>BPh_4^-</math>. Applying this value, the mean ionic activity coefficient in acetonitrile becomes <math>\gamma_{\pm}^2 = 0.359</math>, the <math>K_{s0}^\circ</math> becomes <math>1.02 \times 10^{-3}</math> and the <math>pK_{s0}^\circ = 2.99</math>. Thus, for approximate work, one can choose a <math>pK_{s0}^\circ</math> value of about <math>3.1 \pm 0.1</math>, but it can be described as no better than tentative. A recommended value for solubility product of <math>KBPh_4</math> in acetonitrile must await an experimental determination of the activity coefficients.</p>

## CRITICAL EVALUATION:

The solubility of potassium tetraphenylborate ( $KBPh_4$ ) in acetone has been reported in three publications (1-3). Scott et al. (1) determined the solubility in acetone as part of their study of the solubility in acetone-water mixtures at 301 K (see compilation for acetone-water mixtures). Similarly, Kirgintsev and Kozitskii (2) included the acetone datum in their report on the solubilities of  $KBPh_4$  in acetone-water mixtures at 298.15 K (see compilation for acetone-water mixtures). Subsequently, Kozitskii (3) published the solubilities of  $KBPh_4$  in acetone at 273.15 K and 323.15 K. Thus, no comparison is available between data from two laboratories at any one temperature. However, solubilities at three different temperatures are available from the same laboratory (2, 3). All the available data are summarized in the Table below.

Tentative ValuesSolubilities of  $KBPh_4$  in Acetone at Different Temperatures

T/K	Solubility/mol $dm^{-3}$
273.15	0.196 (3)
298.15	0.171 (2)
301	0.117 (1)*
323.15	0.144 (3)

\*Doubtful value

All of the above solubilities were determined by the method of evaporation and weighing, but the purity of the acetone employed and the temperature control were not the same in the different studies. The solubilities at the temperatures other than 301 K came from the same laboratory and were measured in thoroughly dried acetone (0.007 vol % of water), observing a temperature control of  $\pm 0.05^\circ C$  (2, 3). On the other hand, the datum of Scott et al. (1) at 301 K was determined in acetone which may have contained up to 0.5% water (by volume?) and the solubility value of 0.117 mol  $dm^{-3}$  obtained by them clearly does not belong to the same population as the remaining three data points in the Table.

Since the activity correction would be too uncertain at the solubilities involved here, the corresponding solubility products were not estimated. Instead, a smoothing equation was obtained for the logarithm of the solubility  $S$  as a function of reciprocal absolute temperature, using the three data points at 273.15 K, 298.15 K and 323.15 K (all from the same laboratory (2, 3)):

$\log S = 235/(T/K) - 1.56$ , with a  $\sigma_y = 0.0062$  and a correlation coefficient of 0.994. The solubility value calculated from the above equation for 301 K is 0.165 mol  $dm^{-3}$ . This differs considerably from the 0.117 mol  $dm^{-3}$  value reported by Scott et al. (1). Since low concentrations of water in acetone lead to an increase in the solubility (2) (see compilation) for  $KBPh_4$  in acetone-water mixtures based on Reference (2)), the low solubility value in the study by Scott et al. (1) cannot be rationalized on the basis of the wetness of their acetone. Of course, the unspecified degree of the temperature control and saturation control in the last study, as well as differences between the amounts of residue obtained from the solvent in different studies could account for the discrepancy between the results from the laboratory of Kirgintsev and Kozitskii (2,3) on the one hand and those of Scott et al. (1) on the other hand.

<b>COMPONENTS:</b>  (1) Potassium tetraphenylborate (1-) KC <sub>24</sub> H <sub>20</sub> B; [3244-41-5]  (2) 2-Propanone (acetone); C <sub>3</sub> H <sub>6</sub> O; [67-64-1]	<b>EVALUATOR:</b>  Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979
<b>CRITICAL EVALUATION: (continued)</b>  In conclusion, the only thing that prevents this evaluator from designating the solubility data of Kirgintsev and Kositskii (2) and of Kositskii (3) as the recommended values is the fact that equilibrium for only 6 hours may have been insufficient for complete saturation. Thus, the solubility values at all temperatures except 301 K listed in the Table on the preceding page should be considered as <u>tentative values</u> at this time.  <b>REFERENCES:</b>  1. Scott, A. <b>AUXILIARY INFORMATION</b>					
<b>METHOD/APPARATUS/PROCEDURE:</b>  Evaporation and weighing. Saturated solutions were prepared by stirring mechanically the suspensions in the thermostatted baths for the length of time indicated in the above Table. One liter of the filtrate from the saturated solution was dried by vacuum distillation (~5 hrs keeping the temperature no higher than 40°C). The residue and the column were rinsed out many times with small portions of acetone, which was then collected, evaporated, and the residue, weighed.	<b>SOURCE AND PURITY OF MATERIALS:</b>  Absolute acetone (0.0065 vol % H <sub>2</sub> O) was prep'd by the same method as described on the compilation sheet for $KBPh_4$ in acetone-water at 25°C. $KBPh_4$ obtained by metathesis of KCl and $NaBPh_4$ was purified by double recrystallization from 3:1 acetone-water, evaporation of the acetone, washing of the crystals with water and ether and vacuum drying at 60°C. Water was doubly distilled.				
<b>ESTIMATED ERROR:</b>  Not stated. Temperature control: ±0.05°C

<p>COMPONENTS:</p> <p>(1) Rubidium tetraphenylborate (1-); RbC<sub>24</sub>H<sub>20</sub>B; [5971-93-7]</p> <p>(2) Water; H<sub>2</sub>O; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979</p>
<p>CRITICAL EVALUATION:</p> <p>Five publications containing original data on the solubility of rubidium tetraphenylborate (RbBPh<sub>4</sub>) in aqueous solutions have been reviewed (1-5). Historically the first datum, the conductometrically determined solubility product of RbBPh<sub>4</sub>, <math>K_{s0} = 8 \times 10^{-10}</math> (presumably mol<sup>2</sup> dm<sup>-6</sup>) at 290 K, was rejected (no compilation sheet provided), because nothing was specified in that communication (1). Next was the radiometric determination by Geilman and Gebauhr (2), in which the solubility was reported as <math>4.4 \times 10^{-5}</math> mol dm<sup>-3</sup> at 293.2 K. (The last value was recalculated from raw data in the article by the compiler). In pure water at 298 K, there are the data of Pflaum and Howick (3), where the solubility is given as <math>2.33 \times 10^{-5}</math> mol dm<sup>-3</sup> and of Popovych et al. (4), where it is reported as <math>5.4_2 \times 10^{-5}</math> mol dm<sup>-3</sup>. The last two studies were carried out by UV-spectrophotometry, but their results are unfortunately in poor agreement. Because care was taken in the latter study to control the temperature in the bath to 0.01°C and to ensure saturation by successive analyses days apart until the results checked to 1% or better, the solubility value of <math>5.4 \times 10^{-5}</math> mol dm<sup>-3</sup> is the most reliable we have at the moment at 298.15 K and it should be regarded as the <u>tentative value</u>. Pflaum and Howick (3), on the other hand, gave no details on the temperature control or the saturation procedure. The only other solubility datum at 298 K was determined in a buffer solution, not in pure water (5).</p> <p>REFERENCES:</p> <ol style="list-style-type: none"> <li>1. <p>EXPERIMENTAL VALUES:</p> <p>The solubility is reported both as <math>C_{Rb} = 0.380 \text{ mg cm}^{-3}</math> and as <math>4.5 \times 10^{-5} \text{ mol dm}^{-3}</math>. However, inspection of the raw data (below) suggests that the authors consider only two figures to be significant, i. e. <math>0.38 \text{ mg cm}^{-3}</math> should be the solubility. Using 85.48 for the atomic mass of Rb, this compiler obtains for the solubility <math>C_{Rb} = 4.4 \times 10^{-5} \text{ mol dm}^{-3}</math>. Correspondingly, the solubility product, which the authors report simply as <math>C_{Rb}^2 = 2.0 \times 10^{-9} \text{ mol}^2 \text{ dm}^{-6}</math>, should be <math>K_{s0} = 1.9 \times 10^{-9} \text{ mol}^2 \text{ dm}^{-6}</math> (compiler). Also reported is the rate of dissolution of RbBPh<sub>4</sub> in water:</p> <table data-bbox="364 707 1112 903"> <thead> <tr> <th>Time, hours</th> <th>µg Rb/10 cm<sup>3</sup> of water</th> </tr> </thead> <tbody> <tr> <td>0.5</td> <td>31.5</td> </tr> <tr> <td>1.0</td> <td>33.6</td> </tr> <tr> <td>3.0</td> <td>34.2</td> </tr> <tr> <td>8.0</td> <td>35.5</td> </tr> <tr> <td>20.0</td> <td>37.9</td> </tr> <tr> <td>33.0</td> <td>37.8</td> </tr> </tbody> </table>		Time, hours	µg Rb/10 cm <sup>3</sup> of water	0.5	31.5	1.0	33.6	3.0	34.2	8.0	35.5	20.0	37.9	33.0	37.8

<b>AUXILIARY INFORMATION</b>																																																	
<b>METHOD/APPARATUS/PROCEDURE:</b> Evaporation and weighing. Saturated solutions were prepared by shaking the suspensions in a constant temperature bath for 6 hours. Aliquots were removed through cotton plugs, weighed and the solvent removed by evaporation first under an IR lamp and then by oven-drying to constant weight at 105°C. The solid phase contained no solvent when recrystallized from acetone or acetone-water mixtures.	<b>SOURCE AND PURITY OF MATERIALS:</b> $\text{NaBPh}_4$ ("analytical grade" from the Apolda Co., GDR) was purified by recrystallization from acetone-toluene, followed by dissolution in water, extraction with ether, and removal of the latter <i>in vacuo</i> . The purity of the final $\text{NaBPh}_4$ was no less than 99.6%. $\text{RbBPh}_4$ was prepared by metathesis of $\text{NaBPh}_4$ with $\text{RbCl}$ and purified by double recrystallization from 20% water 80% acetone (probably by vol.). The acetone was slowly evaporated and the precipitate kept for a long time under high vacuum. Acetone was treated with $\text{KMnO}_4$ followed by triple fractionation. Final water content was 0.007 vol. % by Karl Fisher titration.

<b>VARIABLES:</b> One temperature: 25.00°C	<b>PREPARED BY:</b> Orest Popovych
<b>EXPERIMENTAL VALUES:</b> <p>The solubility was reported as <math>C_{\text{BPh}_4^-} = 1.70 \times 10^{-2} \text{ mol dm}^{-3}</math>. The mean molar ionic activity coefficient was calculated using the relationship:</p> $-\log y_{\pm} = \frac{1.64C^{\frac{1}{2}}}{1 + 0.485\lambda C^{\frac{1}{2}}}$ <p>Adopting <math>\lambda = 0.5 \text{ nm}</math> for <math>\text{BPh}_4^-</math> and <math>\lambda = 0.3 \text{ nm}</math> for <math>\text{Rb}^+</math>, the value of <math>y_{\pm}^2 = 0.455</math> and the <math>\text{p}K_{\text{SO}}^{\circ}</math> derived from it was reported as 3.66 (molal scale), i. e., <math>K_{\text{SO}}^{\circ}</math> units are <math>\text{mol}^2 \text{ kg}^{-2}</math>. <math>\text{p}K_{\text{SO}}^{\circ}</math> values on the molar scale (<math>K_{\text{SO}}^{\circ}</math> units of <math>\text{mol}^2 \text{ dm}^{-6}</math>) was not reported, but can be calculated from the molal value via the solvent density, which was <math>0.777 \text{ g ml}^{-1}</math>. On the molar scale, <math>K_{\text{SO}}^{\circ} = 1.31 \times 10^{-4} \text{ mol}^2 \text{ dm}^{-6}</math> and the corresponding <math>\text{p}K_{\text{SO}}^{\circ} = 3.88</math> (compiler). Complete dissociation was assumed, which is generally true for most electrolytes in acetonitrile (1). The molar absorption coefficients for the <math>\text{BPh}_4^-</math> ion were determined to be 3203 and <math>2082 \text{ dm}^3(\text{cm mol})^{-1}</math> at 266 nm and 274 nm, respectively.</p>	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> UV spectrophotometry using a Cary Model 14 spectrophotometer. Saturated solutions were prepared by shaking the suspensions in water-jacketed flasks. After about two weeks of shaking, the suspensions were filtered and the filtrates analyzed spectrophotometrically. The molar absorption coefficients stated above were used to compute the concentration of tetraphenylborate. All work was carried out in deaerated containers and solvents. Differential thermal analysis detected no crystal solvates.	<b>SOURCE AND PURITY OF MATERIALS:</b> Acetonitrile (Matheson, spectroquality) was refluxed for 24 hrs over $\text{CaH}_2$ and fractionally distilled. $\text{RbBPh}_4$ was prepared from $\text{NaBPh}_4$ (Fisher, 99.7%) by metathesis with $\text{RbCl}$ ; it was recrystallized three times from 3:1 acetone-water and dried <u>in vacuo</u> at 80°C.
<b>COMMENTS:</b> The ion-size parameter used for the $\text{BPh}_4^-$ ion in this study was probably too small. If the literature value of 1.2 nm (2) is used instead, $y_{\pm}^2$ becomes 0.500, the $K_{\text{SO}}^{\circ} = 1.44 \times 10^{-4} \text{ mol}^2 \text{ dm}^{-6}$ and $\text{p}K_{\text{SO}}^{\circ} = 3.84$ . Probably a tentative value of $K_{\text{SO}}^{\circ} = 1.4 \times 10^{-4} \text{ mol}^2 \text{ dm}^{-6}$ can be adopted until the activity coefficients are determined experimentally.	<b>ESTIMATED ERROR:</b> Precision $\pm 1\%$ (rel.) Accuracy $\pm 3\%$ (rel.) Temperature control: $\pm 0.01^\circ\text{C}$ <b>REFERENCES:</b> (1) Kay, R. L.; Hales, B. J.; Cunningham, G. P. <i>J. Phys. Chem.</i> <u>1967</u> , <i>71</i> , 3925. (2) Kolthoff, I. M.; Chantooni, M. K. Jr. <i>Anal. Chem.</i> <u>1972</u> , <i>44</i> , 194.

<b>COMPONENTS:</b> (1) Rubidium tetraphenylborate (1-); $\text{RbC}_2\text{H}_2\text{O}_2\text{B}$ ; [5971-93-7] (2) 1,2-Dichloroethane; $\text{C}_2\text{H}_4\text{Cl}_2$ ; [107-06-2]	<b>ORIGINAL MEASUREMENTS:</b> Abraham, M. H.; Danil de Namor, A. F. J. <i>Chem. Soc. Faraday Trans. 1</i> 1976, 72, 955-62.
<b>VARIABLES:</b> One temperature: 25°C	<b>PREPARED BY:</b> Orest Popovych
<b>EXPERIMENTAL VALUES:</b> <p>The authors reported the solubility of <math>\text{RbBPh}_4</math> in 1,2-dichloroethane as:</p> $9.90 \times 10^{-6} \text{ mol dm}^{-3}.$ <p>They used an association constant <math>K_A = 1.70 \times 10^3 \text{ mol}^{-1} \text{ dm}^3</math> and the extended Debye-Hückel equation for the mean ionic activity coefficient with an ion-size parameter <math>\bar{a} = 0.56 \text{ nm}</math> to calculate the standard Gibbs free energy of solution: <math>\Delta G_s^\circ = 13.76 \text{ kcal mol}^{-1} = 57.60 \text{ kJ mol}^{-1}</math> (compiler). From the relationship: <math>\Delta G_s^\circ = -RT \ln K_{s0}^\circ</math>, the solubility product can be calculated as <math>\text{p}K_{s0}^\circ = 10.088</math> where the units of <math>K_{s0}^\circ</math> are <math>\text{mol}^2 \text{ dm}^{-6}</math> (compiler).</p>	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> Saturated solutions prepared by shaking the suspensions at 25°C for several days and analyzing aliquots by evaporation and weighing. Method of temperature control was not specified.	<b>SOURCE AND PURITY OF MATERIALS:</b> The solvent was shaken with anhydrous $\text{K}_2\text{CO}_3$ , passed through a column of basic activated alumina into a distillation flask and fractionated under $\text{N}_2$ through a 3-foot column. At least 10% of distillate was rejected, the rest collected over freshly activated molecular sieve. $\text{RbBPh}_4$ was recryst. from aqueous acetone and dried in a vacuum oven at 60-80°C for several days.
<b>COMMENTS:</b> The above solubility product should be regarded as a <u>tentative value</u> .	<b>ESTIMATED ERROR:</b> Precision of $0.1 \text{ kcal mol}^{-1}$ in $\Delta G_s^\circ$ .

COMPONENTS:	EVALUATOR:
(1) Cesium tetraphenylborate (1-); CsC <sub>24</sub> H <sub>20</sub> B; [3087-82-9] (2) Water; H <sub>2</sub> O; [7732-18-5]	Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. October 1979
CRITICAL EVALUATION:	
<p>There are seven publications dealing with original data pertaining to the solubility of cesium tetraphenylborate (CsBPh<sub>4</sub>) in aqueous solutions (1-7). Two of them, however, report only the solubility product (1,2). Only one of the studies deals with the solubility as a function of the temperature, ionic strength and pH (3). In one publication (7) the solubility was reported in a buffer solution, but not in pure water. What seems to be historically the first datum, the solubility product of CsBPh<sub>4</sub> reported as <math>5 \times 10^{-10}</math> (presumably mol<sup>2</sup> dm<sup>-6</sup>) at 290 K by Rüdorff and Zannier (1), must be rejected because of lack of any experimental details provided, except for the statement that the determination was conductometric. Since the result was reported to one significant figure, no compilation sheet was provided for that original source.</p> <p><u>Solubility at 298 K.</u></p> <p>At 298 K, we have the solubility data of Pflaum and Howick (4), Alexander and Parker (2), expressed in the form of a solubility product, and of Popovych, Gibofsky and Berne (5). All three determinations were by UV-spectrophotometry for the BPh<sub>4</sub><sup>-</sup> ion, but they differ in their reported degree of temperature control and saturation control. Alexander and Parker in reporting a pK<sub>s0</sub> of 8.7 (all solubility products in this evaluation have units of mol<sup>2</sup> dm<sup>-6</sup>) failed to specify how the temperature was controlled and how the existence of saturation was ascertained. However, if we make the usual assumption that the error is 0.1 pK units, the solubility derived from the above K<sub>s0</sub> by simply taking the square root is <math>(4.5 \pm 0.5) \times 10^{-5}</math> mol dm<sup>-3</sup>. This calculation is justified since the above solubility product was reported to be a product of concentrations, not activities. As we can see, the solubility value derived from the datum of Alexander and Parker does not agree with the value of <math>2.79 \times 10^{-5}</math> mol dm<sup>-3</sup> reported by Pflaum and Howick. In the latter study, there is also no indication of how the temperature and the saturation were controlled. Furthermore, the authors used the molar absorption coefficients determined in acetonitrile to analyze the spectra obtained on aqueous solutions. While this procedure may have resulted in a compensation of errors (see evaluation for KBPh<sub>4</sub> in water), a combination of all those shortcomings cannot inspire confidence in the reported solubility value. The work of Popovych et al. (5), on the other hand, was characterized by temperature control to <math>\pm 0.01^\circ\text{C}</math> and repeated analyses days apart until a constant solubility value was attained. The relative precision of determining the solubility of CsBPh<sub>4</sub> in water turned out to be a little lower than the normal <math>\pm 1\%</math> associated with the UV-analysis for tetraphenylborates -- it was <math>\pm 4\%</math>. The solubility was reported as <math>4.0 \times 10^{-5}</math> mol dm<sup>-3</sup> (the last, uncertain, digit dropped by the evaluator). If we restrict the recommendation to two significant digits in the solubility value, it may be just barely justified to average the value of Alexander and Parker (2) and that of Popovych et al. (5) to arrive at the <u>recommended solubility value at 298 K</u> as:</p> $\text{Solubility} = (4.2 \pm 0.2) \times 10^{-5} \text{ mol dm}^{-3}.$ <p>The solubility product calculated as <math>K_{s0}^{\circ} = C^2 y_{\pm}^2</math>, where C is the solubility and <math>y_{\pm}^2</math> is the mean ionic activity coefficient calculated from the Debye-Hückel limiting law, was reported by Popovych et al. (5) as pK<sub>s0</sub><sup>o</sup> = 8.80. It is within 0.1 log units of the value reported by Alexander and Parker (2), but the latter contains no activity correction.</p> <p><u>Solubility at Other Temperatures</u></p> <p>There are two reported solubility values at 293 K. From the work of Geilman and Gebauhr (6), the solubility calculated by the compiler is <math>3.2 \times 10^{-5}</math> mol dm<sup>-3</sup>. At zero ionic strength (presumably meaning in the absence of added inert electrolyte) the solubility value reported by Siska (3) is <math>3.50 \times 10^{-5}</math> mol dm<sup>-3</sup>. Although one might be tempted to average</p>	

COMPONENTS:  (1) Cesium tetraphenylborate (1-); CsC <sub>24</sub> H <sub>20</sub> B; [3087-82-9]  (2) Water; H <sub>2</sub> O; [7732-18-5]	EVALUATOR:  Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. October 1979
---	--

## CRITICAL EVALUATION:

these two results at 293 K, the problem with Siska's data is the very short time of equilibration (3 hours). This length of equilibration proved to be sufficient for the saturation of CsBPh<sub>4</sub> in the rate-of-dissolution study by Geilman and Gebauhr (6), but it is not so as a general rule, in the experience of this evaluator. We have noted in the evaluation for KBPh<sub>4</sub> in water that Siska's (3) solubility values seemed to be too low. If undersaturation did not occur for CsBPh<sub>4</sub>, much valuable information might be salvaged, because Siska's is the only study to date that reported the solubility of CsBPh<sub>4</sub> in water as a function of ionic strength and pH at 293 K as well as the solubility at other temperatures in solutions with ionic strength maintained at 0.1 mol dm<sup>-3</sup>. The latter solubility determinations were reported at 283 K, 303 K, 313 K and 318 K (3). Unfortunately, the only other literature datum on the solubility of CsBPh<sub>4</sub> in a 0.1 mol dm<sup>-3</sup> buffer solution, which is 5.4 x 10<sup>-5</sup> mol dm<sup>-3</sup> at 298 K (7), tends to confirm the undersaturation of Siska's solution.

<b>VARIABLES:</b> Methanol-water composition. $\text{LiCl}$ concentration varied from 0 to 2,000 times the solubility of $\text{CsBPh}_4$ . One temperature: 25.00°C	<b>PREPARED BY:</b> Orest Popovych
<b>EXPERIMENTAL VALUES:</b>  <p>The author reported the mean ionic activities of <math>\text{CsBPh}_4</math> in saturated solutions, which were determined from the variation of the solubility of <math>\text{CsBPh}_4</math> as a function of ionic strength varied by means of <math>\text{LiCl}</math> in the presence of <math>5 \times 10^{-5} \text{ mol dm}^{-3} \text{ NaOH}</math>. For each solvent composition, the activity in saturated solution without added inert electrolyte, <math>a_{\pm,0}</math>, was computed from the functions:</p> $\log C_I = \log a_{\pm,0} - \log y_{\pm,I} \quad \text{and} \quad -\log y_{\pm,I} = A_1 I^{1/2} + A_2 I + A_3 I^{3/2} + \dots$ <p>where <math>y_{\pm}</math> is the mean molar activity coefficient (<math>f_{\pm}</math> in the original) and the subscripts <math>0</math> and <math>I</math> denote solutions without and with added inert electrolyte. Complete dissociation was assumed. The solubilities at different ionic strength were not reported, but their values, as well as those of the activity coefficients at any ionic strength <math>I</math> (in <math>\text{mol dm}^{-3}</math>) can be calculated from the A-coefficients characteristic of the methanol-water mixture tabulated below.</p> <p>The solubility of <math>\text{CsBPh}_4</math> in the pure solvents was not measured due to the extensive decomposition in the absence of added <math>\text{LiCl}</math>, but the corresponding ionic activity, <math>a_{\pm,0}</math>, should be a very good approximation of the solubility in the concentration range involved.</p> <p style="text-align: right;">continued ....</p>	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> Ultraviolet spectrophotometry using a Cary Model 17 spectrophotometer. Saturation was achieved by subjecting the suspensions for 20 minutes to ultrasonic waves (E/MC Corp. Model 450 Ultrasonic Generator) followed by agitation in a thermostatted bath for at least 3 days until constant spectral absorption. Spectra were monitored carefully for indications of decomposition, to which $\text{CsBPh}_4$ solutions are highly susceptible. Sodium hydroxide was added to retard the decomposition.	<b>SOURCE AND PURITY OF MATERIALS:</b> $\text{CsBPh}_4$ was prepared by metathesis of $\text{NaBPh}_4$ and $\text{CsCl}$ (both from Alfa Inorganic) and purified by triple recrystallization from a 3:1 acetone-water mixture. It was dried <u>in vacuo</u> at 80°C for 24 hours. $\text{LiCl}$ (Baker Analyzed Reagent) was used without purification after drying <u>in vacuo</u> at 110°C for 24 hours. Certified ACS spectroanalyzed methanol (Fisher Scientific Co.) was used as received. The mass% of methanol-water mixtures was determined from the measured <u>densities and literature data (1)</u> . <b>ESTIMATED ERROR:</b> The relative precision of $a_{\pm,0}$ is tabulated. Temperature control: $\pm 0.01^\circ\text{C}$ .

<p>COMPONENTS:</p> <p>(1) Cesium tetrphenylborate (1-); CsC<sub>24</sub>H<sub>20</sub>B; [3087-82-9]</p> <p>(2) Acetonitrile; C<sub>2</sub>H<sub>3</sub>N; [75-05-8]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. October 1979</p>
<p>CRITICAL EVALUATION:</p> <p>There are only two original data on the solubility of cesium tetraphenylborate (CsBPh<sub>4</sub>) in acetonitrile, both at 298 K. Alexander and Parker (1) reported the solubility in the form <math>pK_{s0} = 3.1</math>, where the <math>K_{s0}</math> was a product of ionic concentrations, not activities (all <math>K_{s0}</math> values in this evaluation have units of mol<sup>2</sup> dm<sup>-6</sup>). On the assumption that the above <math>pK_{s0}</math> has a precision of <math>\pm 0.1</math> units, the compiler estimated the solubility to be <math>(K_{s0})^{1/2} = (2.8 \pm 0.3) \times 10^{-2}</math> mol dm<sup>-3</sup>. The analytical method was either UV-spectrophotometry, or titration of BPh<sub>4</sub><sup>-</sup> with Ag<sup>+</sup>. Unfortunately, no experimental details are provided by the authors as to the extent of temperature control and the manner in which the attainment of saturation was ascertained. Popovych, Gibofsky and Berne (2) reported a solubility value of <math>1.68 \times 10^{-2}</math> mol dm<sup>-3</sup>, which differs greatly from that of Alexander and Parker (1). Considering that Popovych et al. (2) controlled the temperature of the bath to 0.01°C and that saturation (as well as possible decomposition) were monitored by successive analyses days apart until the results checked to 1% or better, their solubility value would seem to be the preferred one of the two. However, the <u>solubility of <math>1.68 \times 10^{-2}</math> mol dm<sup>-3</sup></u> should be considered no better than <u>tentative</u> at this time.</p> <p>The thermodynamic solubility product estimated by Popovych et al. (2) was reported in the form <math>pK_{s0}^{\circ} = 3.67</math> (weight basis), i. e., <math>K_{s0}^{\circ}</math> units of mol<sup>2</sup> kg<sup>-2</sup>. Based on volume units, i. e., mol dm<sup>-3</sup>, the <math>pK_{s0}^{\circ}</math> would be 3.89 (evaluator). The activity correction was made via the calculated activity coefficient of <math>y_{\pm}^2 = 0.456</math> derived from the Debye-Hückel equation with ion-size parameter shown on the compilation sheet. One could argue, however, that using <math>\dot{a} = 0.5</math>nm for the BPh<sub>4</sub><sup>-</sup> ion is not realistic; for example, Kolthoff and Chantooni (3) preferred a value of <math>\dot{a} = 1.2</math>nm. Using the latter value in our calculation leads to a <math>y_{\pm}^2 = 0.501</math> and a <math>pK_{s0}^{\circ} = 3.85</math> (volume basis).</p> <p>REFERENCES:</p> <ol style="list-style-type: none"> <li>Alexander, R.; Parker, A. <p>COMPONENTS:</p> <p>(1) Ammonium tetraphenylborate (1-);  <math>C_{24}H_{20}BN</math>; [14637-34-4]</p> <p>(2) Water; <math>H_2O</math>; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of  Chemistry, City University of  New York, Brooklyn College,  Brooklyn, N. Y. 11210, U. S. A.  November 1979</p>
<p>CRITICAL EVALUATION:</p> <p>The solubility of ammonium tetraphenylborate (<math>NH_4BPh_4</math>) in aqueous solutions was published in four articles (1-4). In the two studies by Pflaum and Howick (1,2), the solubility was determined at 298 K by uv-spectrophotometry, but the two reported results differed drastically, being <math>1.07 \times 10^{-4} \text{ mol dm}^{-3}</math> and <math>2.88 \times 10^{-4} \text{ mol dm}^{-3}</math>, respectively. Such huge discrepancy cannot be rationalized on the basis of any of the obvious shortcomings in the reported work. Thus, while it is true that the method and the precision of the temperature control were not specified in either of the articles, we can readily see from Siska's (3) data that the solubility of <math>NH_4BPh_4</math> in aqueous solutions varies on the average by about <math>7 \times 10^{-6} \text{ mol dm}^{-3}</math> per degree in the 293-303 K range. It is also true that in their first study Pflaum and Howick (1) used absorption coefficients <math>\epsilon_{\text{max}}</math> for the <math>BPh_4^-</math> ion which were characteristic of acetonitrile solutions. Although nothing was specified with respect to the absorption coefficients in their subsequent article (2), it is probable that the <math>\epsilon_{\text{max}}</math> values characteristic of acetonitrile solutions were used to calculate solubilities in aqueous solutions from absorption data throughout their work. The molar <math>\epsilon_{\text{max}}</math> values used by Pflaum and Howick (1) were <math>3.225 \times 10^3</math> and <math>2.110 \times 10^3</math> at 266 nm and 274 nm, respectively, while the corresponding values reported for aqueous solutions are <math>3.25 \times 10^3</math> and <math>2.06 \times 10^3</math>, respectively (5). (All molar absorption coefficients are in the units of <math>\text{dm}^3 (\text{cm mol})^{-1}</math>). Thus, if Pflaum and Howick averaged the solubility values determined at the two wavelengths, they benefitted from a compensation of errors, which in the case of the solubility of <math>KBPh_4</math> in water (1) led to a result in excellent agreement with other literature data (see critical evaluation for <math>KBPh_4</math> in water). Certainly, the discrepancies between aqueous and acetonitrile <math>\epsilon_{\text{max}}</math> values, which are of the order of 1-3%, could not account for the unreasonably large difference between the two solubility values reported in the two studies by Pflaum and Howick (1,2).</p> <p>The third source of information on the solubility of <math>NH_4BPh_4</math> in aqueous solutions -- the article by Siska (3) -- can offer only an indirect check on the validity of the results from the previous two studies. This is so because at zero ionic strength Siska reported a solubility only at 293 K, which was <math>2.52 \times 10^{-4} \text{ mol dm}^{-3}</math>. An estimate of the solubility at 298 K can be made from Siska's data on the variation of the solubility as a function of the temperature, but at an ionic strength of <math>0.1 \text{ mol dm}^{-3}</math> maintained by sodium sulfate. If we use a linear interpolation in the function of <math>\log C</math> vs. <math>T^{-1}</math>, where <math>C</math> is the solubility, the interpolated solubility value at 298.15 K turns out to be <math>3.27 \times 10^{-4} \text{ mol dm}^{-3}</math> (at the ionic strength of <math>0.1 \text{ mol dm}^{-3}</math>). If the Davies equation is used to estimate the activity coefficient: <math>-\log \gamma_{\pm} = [0.509 I^{1/2} / (1 + I^{1/2})] + 0.1 I</math>, where <math>I</math> is the ionic strength, we obtain for a <math>0.1 \text{ mol dm}^{-3}</math> solution the value <math>\gamma_{\pm} = 0.771</math>, from which the solubility at zero ionic strength is estimated to be <math>2.52 \times 10^{-4} \text{ mol dm}^{-3}</math>.</p> <p>McClure and Rechnitz (4) measured the solubility of <math>NH_4BPh_4</math> in a <math>0.1 \text{ mol dm}^{-3}</math> tris(hydroxymethyl)aminomethane buffer solution at 298.0 K and reported it as <math>3.4 \times 10^{-4} \text{ mol dm}^{-3}</math>. This is in fair agreement with the result interpolated above from Siska's data, but a precise comparison and a calculation of the solubility at zero ionic strength from the data of McClure and Rechnitz is impossible, because the ionic strength of their buffer solution is not known exactly. Unfortunately, Siska's solubility values are very likely to be too low due to undersaturation (the suspensions were agitated for only 3 hours). They were definitely too low in the case of <math>KBPh_4</math> in water. Nevertheless, the data of Siska as well as of McClure and Rechnitz suggest that it must be the second reported solubility value</p>	

<b>COMPONENTS:</b>  (1) Ammonium tetraphenylborate (1-); C <sub>24</sub> H <sub>20</sub> BN; [14637-34-3]  (2) Water; H <sub>2</sub> O; [7732-18-5]	<b>EVALUATOR:</b>  Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. November 1979
<b>CRITICAL EVALUATION:</b> (continued)  by Howick and Pflaum (2), i.e., $2.88 \times 10^{-4}$ mol dm <sup>-3</sup> , that we should place our reliance on at 298 K. Of course, the above value should be regarded as <u>tentative</u> at best. At other temperature, the only available solubility values are those reported by Siska (3), which are probably too low due to undersaturation.

<b>VARIABLES:</b>  One temperature: 25.00°C	<b>PREPARED BY:</b>  Orest Popovych
<b>EXPERIMENTAL VALUES:</b>  The authors report the solubility of triisoamyl-n-butylammonium tetraphenylborate (TAB BPh <sub>4</sub> ) in water determined directly by uv-spectrophotometry in the presence of 10 <sup>-5</sup> mol dm <sup>-3</sup> NaOH as an uncertain value:  $C = 1.4 \times 10^{-7} \text{ mol dm}^{-3}.$  Because of the tendency of TAB BPh <sub>4</sub> to decompose upon prolonged equilibration with water, the authors also calculated the solubility indirectly from the transfer activity coefficients (medium effects) as follows:  $\log m_{y_{\pm}}^2(\text{TAB BPh}_4) = \log m_{y_{\pm}}^2(\text{TAB Pi}) + \log m_{y_{\pm}}^2(\text{KBPh}_4) - \log m_{y_{\pm}}^2(\text{KPi}) \quad (1)$ and $\log m_{y_{\pm}}^2 = \log \frac{K_{\text{SO}}^{\circ}(\text{water})}{K_{\text{SO}}^{\circ}(\text{methanol})} \quad (2)$  Substituting on the rhs of Equation (1) values of $m_{y_{\pm}}^2$ obtained from experimental determinations of solubilities and Equation (2), the authors obtained:  $\log m_{y_{\pm}}^2(\text{TAB BPh}_4) = -5.398 + (-2.300) - 1.101 = -8.799$  Using the above result as well as $K_{\text{SO}}^{\circ}(\text{methanol}) = 7.36 \times 10^{-6}$ in Equ. (2), they obtained $K_{\text{SO}}^{\circ}(\text{water}) = 1.17 \times 10^{-14} \text{ mol}^2 \text{ dm}^{-6}$ (units by compiler), from which the solubility $C = 1.08 \times 10^{-7} \text{ mol dm}^{-3}$ .  In the above equations, the transfer activity coefficients refer to the transfer from water to methanol. Pi = picrate ion.

<b>VARIABLES:</b>  One temperature: 25.00°C	<b>PREPARED BY:</b>  Orest Popovych
<b>EXPERIMENTAL VALUES:</b> The authors report the solubility of tetra- <i>n</i> -butylammonium tetra-phenylborate (Bu <sub>4</sub> N BPh <sub>4</sub> ) in water determined directly by uv-spectrophotometry in the presence of 10 <sup>-5</sup> M NaOH as an uncertain value: $C = 3.4 \times 10^{-6} \text{ mol dm}^{-3}.$ Because of the tendency of Bu <sub>4</sub> N BPh <sub>4</sub> to decompose upon prolong equilibration with water, the authors also calculated the solubility indirectly, via transfer activity coefficients (medium effects) as follows: $\log m_{\pm}^2(\text{Bu}_4\text{N BPh}_4) = \log m_{\pm}^2(\text{Bu}_4\text{N Pi}) + \log m_{\pm}^2(\text{KBPh}_4) - \log m_{\pm}^2(\text{KPi}) \quad (1)$ where $m_{\pm}$ is the mean molar medium effect for the electrolyte in methanol (i.e., the activity coefficient for the transfer water → methanol) and Pi is the picrate ion. Values of $\log m_{\pm}$ for the electrolytes on the rhs of the above equation were obtained from the experimentally determined solubility products: $\log m_{\pm}^2 = \log \frac{K_{\text{SO}}^{\circ}(\text{water})}{K_{\text{SO}}^{\circ}(\text{methanol})} \quad (2)$ then: $\log m_{\pm}^2(\text{Bu}_4\text{N BPh}_4) = -4.438 + (-2.300) - 1.101 = -7.839$ introducing in equation (2) the above result as well as $K_{\text{SO}}^{\circ} = 4.62 \times 10^{-6} \text{ mol}^2 \text{ dm}^{-6}$ in methanol, the authors obtained $K_{\text{SO}}^{\circ} = 6.69 \times 10^{-14}$ (water) from which the solubility $C = 2.59 \times 10^{-7} \text{ mol dm}^{-3}$ .	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> UV spectrophotometry using a Cary Model 14 spectrophotometer. Saturation achieved by shaking the salt suspensions for 2 weeks in water-jacketed flasks. Solutions filtered and analyzed at 266 and 274 nm. All solutions and containers were deaerated.	<b>SOURCE AND PURITY OF MATERIALS:</b> Bu <sub>4</sub> N BPh <sub>4</sub> was synthesized and purified as described in the literature (1).  <b>ESTIMATED ERROR:</b> Not specified. <p>COMPONENTS:</p> <p>(1) Tetramethylammonium tetraphenylborate (1-); <math>C_{28}H_{32}BN</math>; [15525-13-0]</p> <p>(2) Water; <math>H_2O</math>; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. March 1980</p>
<p>CRITICAL EVALUATION:</p> <p>Although the solubility of tetramethylammonium tetraphenylborate in water was reported from two different studies (1,2), there is no doubt as to which of them is the more reliable. Thus, the solubility reported by Zeidler (1) as 0.05% is not only ambiguous and expressed to one significant digit, but also was determined by an unspecified analytical method at an unspecified (presumably room) temperature. On the other hand, the value reported by Howick and Pflaum (2) as <math>4.3 \times 10^{-5}</math> mol <math>dm^{-3}</math> was obtained by uv-spectrophotometry at 298 K under conditions where saturation was ascertained.</p> <p>There are unfortunately two drawbacks in the latter study as well. First, the extent to which the temperature was controlled is not specified. Second, it is not clear which values of the absorption coefficients <math>\epsilon_{max}</math> for the tetraphenylborate ion were used to calculate the solubilities. This question arises because of the fact that in an earlier study Pflaum and Howick (3) used <math>\epsilon_{max}</math> values characteristic of acetonitrile solutions to calculate solubilities in aqueous solutions from their absorption data. The molar <math>\epsilon_{max}</math> values used by Pflaum and Howick (3) were <math>3.225 \times 10^3</math> and <math>2.110 \times 10^3</math> at 266 nm and 274 nm, respectively, while the corresponding values reported for aqueous solutions are <math>3.25 \times 10^3</math> and <math>2.06 \times 10^3</math>, respectively (4). (All molar absorption coefficients are in the units of <math>dm^3 (cm mol)^{-1}</math>). Thus, if Howick and Pflaum (2) averaged the solubility values determined at the two wavelengths, they benefitted from a compensation of errors, which in the case of the solubility of <math>KBPh_4</math> in water (3) led to excellent agreement with other literature data (see critical evaluation for <math>KBPh_4</math> in water). However, one cannot be certain that a similar compensation of errors was involved in the case of tetramethylammonium tetraphenylborate. Consequently, the solubility of <math>4.3 \times 10^{-5}</math> mol <math>dm^{-3}</math> at 298 K must be regarded as a highly <u>tentative value</u>.</p>

<b>EXPERIMENTAL VALUES:</b> <p>The authors reported the solubility of <math>Pr_4NBPh_4</math> in 1,2-dichloroethane as: <math>1.01 \times 10^{-1} \text{ mol dm}^{-3}</math>. Using an estimated association constant of <math>2.10 \times 10^3 \text{ mol}^{-1} \text{ dm}^3</math> and an ion-size parameter of <math>a = 0.66 \text{ nm}</math> with which to calculate the mean ionic activity coefficient from the extended Debye-Hückel equation, they obtained for the standard Gibbs free energy solution:</p> $G_s^\circ = 6.33 \text{ kcal mol}^{-1} = 26.5 \text{ kJ mol}^{-1} \text{ (compiler).}$ <p>The solubility (ion-activity) product of <math>Pr_4NBPh_4</math> can be calculated from relationship: <math>\Delta G_s^\circ = -RT \ln K_{s0}^\circ</math>, yielding <math>pK_{s0}^\circ = 4.640</math>, where <math>K_{s0}^\circ</math> units are <math>\text{mol}^2 \text{ dm}^{-6}</math> (compiler).</p>	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> Evaporation and weighing. Saturated solutions prepared by shaking the suspensions for several days at 25°C. No solvate was detected. Method of temperature control was not specified.	<b>SOURCE AND PURITY OF MATERIALS:</b> The solvent was shaken with anhydrous $K_2CO_3$ , passed through a column of basic activated alumina into distillation flask and fractionated under $N_2$ through a 3-foot column. At least 10% of distillate was rejected, the rest collected over freshly activated molecular sieve. $Pr_4NBPh_4$ was recrystallized from aqueous acetone and vacuum dried for several days at 60-80°C.
	<b>ESTIMATED ERROR:</b> Precision of $0.1 \text{ kcal mol}^{-1}$ in $\Delta G_s^\circ$ .

<b>VARIABLES:</b> One temperature: 25°C	<b>PREPARED BY:</b> Orest Popovych
<b>EXPERIMENTAL VALUES:</b> <p>The solubility of trimethylammonium tetraphenylborate in water was reported as:</p> <p style="text-align: center;"><math>3.87 \times 10^{-4} \text{ mol dm}^{-3}</math>.</p> <p>For a critical evaluation of the data from this study, see the evaluation for <math>NH_4BPh_4</math> in water.</p>	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> <p>Saturated solutions were prepared both by agitating the suspensions continuously at 25°C and by agitating them first for a 0.5 hr at 40-50°C and then cooling to 25°C. When equilibrium was attained, the filtered solutions were analyzed for the <math>BPh_4^-</math> anion by UV spectrophotometry, using a Cary Model 11 recording spectrophotometer. The method of temperature control was not stated.</p>	<b>SOURCE AND PURITY OF MATERIALS:</b> <p>See the compilation for <math>NH_4BPh_4</math> in water based on the same reference. The amine hydrochloride used to prepare the tetraphenylborate was an Eastman White Label product.</p> <b>ESTIMATED ERROR:</b> <p>Nothing specified.</p> <b>REFERENCES:</b>

<p>COMPONENTS:</p> <p>(1) Tris(o-phenanthroline)ruthenium (II) tetraphenylborate (1-); <math>\text{RuC}_{84}\text{H}_{64}\text{B}_2\text{N}_6</math>;</p> <p>(2) Organic Solvents</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. October 1979</p>
<p>CRITICAL EVALUATION:</p> <p>There is only one published value for the solubility of tris(o-phenanthroline)ruthenium(II) tetraphenylborate in each of the 22 organic solvents at 298 K as given in the compilations that follow (1). Unfortunately, the accuracy of these solubility values is probably adversely affected by two shortcomings: 1) The molar absorption coefficient of the cation, which was used to calculate the solubility in different organic solvents was characteristic of aqueous solutions and 2) the precision of the temperature control was not specified. Consequently, the reported solubility values must be designated as no better than <u>tentative</u>.</p> <p>REFERENCE:</p> <p>1. Takamatsu, T. <i>Bull. Chem. Soc. <p>COMPONENTS:</p> <p>(1) Silver tetraphenylborate (1-); AgC<sub>24</sub>H<sub>20</sub>B; [14637-35-5]</p> <p>(2) Water; H<sub>2</sub>O; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, The City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979</p>
<p>CRITICAL EVALUATION:</p> <p>The solubility of silver tetraphenylborate (AgBPh<sub>4</sub>) in water proved to be exceptionally elusive. It is too low for reliable direct determination by UV-spectrophotometry, since the molar absorptivity of the BPh<sub>4</sub><sup>-</sup> ion in water at the characteristic 266-nm peak is only <math>3.25 \times 10^3 \text{ dm}^3 (\text{cm mol})^{-1}</math>, while the reported solubility generally ranges between <math>10^{-7}</math> and <math>10^{-9} \text{ mol dm}^{-3}</math>. Furthermore, the reduction of the silver ion in AgBPh<sub>4</sub> suspensions by light and possibly by organic impurities creates additional difficulties regardless of the analytical method employed.</p> <p>Historically, the first to report a solubility product for AgBPh<sub>4</sub> in water was Haviř (1). Noting that direct potentiometry with a silver electrode in saturated AgBPh<sub>4</sub> solutions led to irreproducible results, he resorted to potentiometric determinations in the presence of <math>\sim 0.01 \text{ mol dm}^{-3}</math> NaBPh<sub>4</sub>, which at 293 K yielded a <math>K_{\text{SO}} = 4.0 \times 10^{-14}</math> (all solubility products in this evaluation have units of <math>\text{mol}^2 \text{ dm}^{-6}</math>). Popovych (2) repeated Haviř's work at several concentrations of NaBPh<sub>4</sub> at 298 K, obtaining a <math>K_{\text{SO}} = 4.07 \times 10^{-14}</math>. (The <math>\text{p}K_{\text{SO}}</math> values from the work of both Haviř (1) and Popovych (2) are 13.4). Alexander et al. (3) reported a <math>\text{p}K_{\text{SO}} = 11.1</math> at 298 K and at an ionic strength of <math>0.01 \text{ mol dm}^{-3}</math> on the basis of a potentiometric titration of a tetraphenylborate solution with silver ion.</p> <p>Kolthoff and Chantooni (4) questioned all of the above results on the grounds that the values for the transfer activity coefficients (medium effects) for the transfer of silver and tetraphenylborate ions from water to methanol required a <math>\text{p}K_{\text{SO}}^{\circ}</math> value of AgBPh<sub>4</sub> in water of the order of 17.5. They repeated Popovych's (2) experiments, obtaining a <math>\text{p}K_{\text{SO}}</math> value of <math>14.3 \pm 0.2</math>, from which they concluded that the silver-silver tetraphenylborate electrode behaves abnormally in aqueous solutions, probably because it is not wetted by water (4). Instead, Kolthoff and Chantooni (4) determined the solubility product of AgBPh<sub>4</sub> in water from the chemical-exchange experiments in which a solution of NaBPh<sub>4</sub> was equilibrated with solid AgI and a solution of NaI was equilibrated with solid AgBPh<sub>4</sub>. On this basis they reported a <math>\text{p}K_{\text{SO}}^{\circ} = 17.2 \pm 0.2</math> at 298K. The latter is probably the best value available to date, but in view of the fact that it has not yet been corroborated by another method or by work from another laboratory that value must be described for now as <u>tentative</u>.</p> <p>Since the activity correction in this case is certainly negligible, the solubility of AgBPh<sub>4</sub> in water can be estimated as <math>(K_{\text{SO}}^{\circ})^{1/2}</math>, which leads to the value of <u>Solubility</u> = <math>(2.5 \pm 0.3) \times 10^{-9} \text{ mol dm}^{-3}</math> at 298 K. It is, of course, also <u>tentative</u>. In view of this, the solubility of <math>7.6 \times 10^{-6} \text{ mol dm}^{-3}</math> reported by McClure and Rechnitz (5) for a THAM buffer solution is much too high.</p> <p>REFERENCES:</p> <ol style="list-style-type: none"> <li>Haviř, J. <i>Collect. <b>VARIABLES:</b>  One temperature: 25.00°C	<b>PREPARED BY:</b>  Orest Popovych
<b>EXPERIMENTAL VALUES:</b>  The solubility of $\text{AgBPh}_4$ in the mixture consisting of 50.0% toluene, 49.5% isopropyl alcohol and 0.5% water by volume known as the ASTM medium* was reported as:  $C = 5.40 \times 10^{-5} \text{ mol dm}^{-3}.$ The corresponding ionic concentration in the saturated solution was reported to be:  $C\alpha = 2.48 \times 10^{-5} \text{ mol dm}^{-3}.$ The molar activity coefficient for the electrolyte in the ASTM medium at 25°C is given by the limiting Debye-Hückel expression as:  $\log y_{\pm}^2 = -31.44(C\alpha)^{\frac{1}{2}}.$ The solubility product for $\text{AgBPh}_4$ in the ASTM medium calculated from the above results in the form: $K_{\text{SO}}^{\circ} = (C\alpha y_{\pm})^2$ was reported as:  $K_{\text{SO}}^{\circ} = 4.29 \times 10^{-10} \text{ mol}^2 \text{ dm}^{-6}.$ The degree of dissociation $\alpha$ was calculated from the Wirth equation (1):  $\alpha = \frac{1000 \kappa}{C[\Lambda^{\infty} - S(1000 \kappa/\Lambda^{\infty})]^{\frac{1}{2}}},$ <p style="text-align: right;">...continued</p>	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> Electrolytic conductivity of saturated and diluted solutions in conjunction with equations developed in this article. The measurements were carried out on a Wayne-Kerr Universal Bridge B221 with a platinum cell. Saturated solutions were prepared by shaking for at least 2 weeks on a Burrell wrist-action shaker in water-jacketed flasks.	<b>SOURCE AND PURITY OF MATERIALS:</b> $\text{AgBPh}_4$ was prepared by metathesis of exactly stoichiometric amounts of aqueous $\text{AgNO}_3$ and purified $\text{KBPh}_4$ dissolved in a minimum of acetone. The precipitate was washed by decantation first with water, then with ASTM solvent. The purification of solvents was described elsewhere (2).  <b>ESTIMATED ERROR:</b> None specified, but the precision in the solubility was about $\pm 6\%$ (compiler). Temperature: $\pm 0.01^\circ\text{C}$ .  <b>REFERENCES:</b> (1) Wirth, H. E. <i>J. Phys. Chem.</i> <u>1961</u> , <i>65</i> , 1441. (2) Popovych, O. <i>J. Phys. Chem.</i> <u>1962</u> , <i>66</i> , 915.

<p>COMPONENTS:</p> <p>(1) Silver tetraphenylborate (1-); AgC<sub>24</sub>H<sub>20</sub>B; [14637-35-5]</p> <p>(2) Acetonitrile; C<sub>2</sub>H<sub>3</sub>N; [75-05-8]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, The City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979</p>
<p>CRITICAL EVALUATION:</p> <p>The solubility product of silver tetraphenylborate (AgBPh<sub>4</sub>) in acetonitrile was reported in three studies, all determinations being at 298 K (1-3). In their first publication, Alexander et al. (1) reported a <math>pK_{s0}^{\circ} = 7.2</math> (all <math>K_{s0}</math> units are mol<sup>2</sup> dm<sup>-6</sup>). It was determined by potentiometric titration of BPh<sub>4</sub><sup>-</sup> with Ag<sup>+</sup> at a constant ionic strength of 0.01 mol dm<sup>-3</sup> using a silver electrode. The revised value from the same laboratory was <math>pK_{s0}^{\circ} = 7.5</math> (2). It was also derived from analogous potentiometric titrations, but was based on additional measurements and activity corrections from the Davies equation (see compilation). Unfortunately, neither temperature control, nor a method of ascertaining saturation were mentioned in the above two publications. Fortunately, at the low levels of precision involved, fine temperature control is not likely to be critical.</p> <p>Kolthoff and Chantooni (3) published a <math>pK_{s0}^{\circ}</math> value of 7.7, using the same potentiometric method as for AgBPh<sub>4</sub> in methanol (see compilation). Although one cannot be sure of the specifics, this implies that activity coefficients may have been calculated by the Debye-Hückel equation with ion-size parameters and that a temperature control of ±1°C was probably maintained, since both measures were observed in the methanol study (4). The analysis was carried out on saturated solutions.</p> <p>Although the <math>pK_{s0}^{\circ}</math> of 7.7 may be the best available datum to date, its accuracy was estimated by the authors as not better than ±0.2 pK units. In view of this we may feel justified to average their result with the <math>pK_{s0}^{\circ}</math> of 7.5 reported by Alexander et al. (2), obtaining as the <u>tentative</u> value <math>pK_{s0}^{\circ} = 7.6</math>.</p> <p>Assuming as usual an error of 0.1 <math>pK_{s0}^{\circ}</math> units, we can estimate the solubility as <math>(K_{s0})^{1/2}</math>: Solubility = <math>(1.6 \pm 0.2) \times 10^{-4}</math> mol dm<sup>-3</sup>. This, of course, is an estimate which neglects the unknown activity correction introduced originally in the calculation of <math>K_{s0}^{\circ}</math>, so that the solubility of AgBPh<sub>4</sub> in acetonitrile cannot even be designated as tentative at this time.</p> <p>REFERENCES:</p> <ol style="list-style-type: none"> <li>Alexander, R.; Ko, E. <p>COMPONENTS:</p> <p>(1) Silver tetraphenylborate (1-); AgC<sub>24</sub>H<sub>20</sub>B; [14637-35-5]</p> <p>(2) N,N-Dimethylformamide; C<sub>3</sub>H<sub>7</sub>NO; [68-12-2]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, The City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979</p>
<p>CRITICAL EVALUATION:</p> <p>The solubility product of silver tetraphenylborate (AgBPh<sub>4</sub>) in N,N-dimethylformamide at 298 K was published in three literature sources (1-3). Both values reported by Alexander et al. (1, 2) were derived from potentiometric titrations of BPh<sub>4</sub><sup>-</sup> with Ag<sup>+</sup> using a silver electrode. In their first study, a concentration solubility product was reported in the form <math>pK_{s0}^{\circ} = 6.7</math> (1). (All <math>K_{s0}</math> units are mol<sup>2</sup> dm<sup>-6</sup>). In the follow-up study from the same laboratory, which involved additional determinations and activity corrections via the Davies equation (see compilation), the revised value was <math>pK_{s0}^{\circ} = 7.1</math> (2). Unfortunately, neither temperature control, nor a method of ascertaining saturation were mentioned in the above two publications. However, at the low levels of precision involved, a fine temperature control may not be critical.</p> <p>Kolthoff and Chantooni (3) reported a <math>pK_{s0}^{\circ} = 7.5</math> determined by the same potentiometric procedure as for AgBPh<sub>4</sub> in methanol (see compilation). If this means that activity coefficients were calculated from the Debye-Hückel equation with ion-size parameters and that temperature was controlled to ±1°C, as was done on both counts in methanol (4), their result may be slightly more reliable than that of Alexander et al. (2). At least the analysis was carried out in definitely saturated solutions, as opposed to the assumed saturation at an electrode in the course of a potentiometric precipitation titration. Thus the <math>pK_{s0}^{\circ} = 7.5</math> may be described as the tentative value for AgBPh<sub>4</sub> in N,N-dimethylformamide. The corresponding solubility taken as <math>(K_{s0}^{\circ})^{1/2} = (1.8 \pm 0.2) \times 10^{-4}</math> mol dm<sup>-3</sup>, assuming a precision of 0.1 units in <math>pK_{s0}^{\circ}</math>. Of course, this estimate neglects an unknown activity correction contained in the <math>K_{s0}^{\circ}</math>, so that it cannot even be described as tentative. For example, if we use the above estimate of the solubility to compute the activity coefficient from the Davies equation, the result is <math>y_{+} = 0.954</math> and the "corrected" solubility value becomes <math>1.9 \times 10^{-4}</math> mol dm<sup>-3</sup>.</p> <p>REFERENCES:</p> <ol style="list-style-type: none"> <li>Alexander, R.; Ko, E.  Chemistry, The City University of  
 New York, Brooklyn College,  
 Brooklyn, N. Y. 11210, U. S. A.  
 September 1979

## CRITICAL EVALUATION:

The solubility product of silver tetraphenylborate ( $\text{AgBPh}_4$ ) in dimethylsulfoxide was reported in three literature sources, all determinations being at 298 K (1-3). Using either potentiometry or UV-spectrophotometry, Alexander et al. (1) determined a  $\text{pK}_{\text{SO}}^{\circ} = 4.6$  from the product of ionic concentrations (all  $\text{K}_{\text{SO}}$  units are  $\text{mol}^2 \text{dm}^{-6}$ ). A subsequent report from the same laboratory (2) based upon potentiometric titration of  $\text{BPh}_4^-$  with  $\text{Ag}^+$  using a silver electrode and activity corrections by the Davies equation (see compilation) gave a  $\text{pK}_{\text{SO}}^{\circ} = 5.1$ . It is difficult to evaluate these results, as neither temperature control, nor a method for ascertaining saturation have been specified.

Kolthoff and Chantooni (3) reported a potentiometric  $\text{pK}_{\text{SO}}^{\circ}$  value of 4.7<sub>5</sub> and a conductometric value of 4.7, with an estimated accuracy of  $\pm 0.2$  pK units. The analysis was carried out on filtered saturated solutions in both cases, but nothing is mentioned about activity corrections or temperature control. In analogous work reported from the same laboratory (4), the temperature control was  $\pm 1^\circ\text{C}$  and activity coefficients were calculated from a Debye-Hückel equation with ion-size parameters. Thus, the value  $\text{pK}_{\text{SO}}^{\circ} = 4.7_5$  can be considered no better than tentative at this time.

In view of the uncertainty in the activity corrections incorporated in the above  $\text{pK}_{\text{SO}}^{\circ}$  value, the solubility must be derived from the concentration  $\text{pK}_{\text{SO}}$  determined by Alexander et al. (1). Assuming an error of 0.1 pK units in the value 4.6, we obtain for the solubility  $(5.0 \pm 0.6) \times 10^{-3} \text{ mol dm}^{-3}$ . (evaluator). This solubility value must be described as highly tentative.

<b>REFERENCES:</b>	

<p>COMPONENTS:</p> <p>(1) Silver tetraphenylborate (1-); AgC<sub>24</sub>H<sub>20</sub>B; [14627-35-5]</p> <p>(2) Methanol; CH<sub>4</sub>O; [67-56-1]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, The City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979</p>
<p>CRITICAL EVALUATION:</p> <p>Only two publications reported the solubility product of silver tetraphenylborate (AgBPh<sub>4</sub>) in methanol, both at 298 K (1, 2). The formal (concentration) solubility product determined by Alexander et al. (1) from a potentiometric titration of BPh<sub>4</sub><sup>-</sup> with AgNO<sub>3</sub> using a silver electrode at ionic strength kept constant at 0.01 mol dm<sup>-3</sup> was expressed as pK<sub>SO</sub><sup>o</sup> = 13.2 (all K<sub>SO</sub><sup>o</sup> units in this evaluation are mol<sup>2</sup> dm<sup>-6</sup>).</p> <p>Kolthoff and Chantooni (2) employed both potentiometry in the presence of NaBPh<sub>4</sub> and chemical-exchange reactions in which either solid AgBr was equilibrated with a solution of NaBPh<sub>4</sub> or solid AgBPh<sub>4</sub> was equilibrated with a solution of NaBr to determine the pK<sub>SO</sub><sup>o</sup> of AgBPh<sub>4</sub>. They obtained the same result by both methods: pK<sub>SO</sub><sup>o</sup> = 14.4 ± 0.01.</p> <p>Despite the fact that the above result was obtained by two independent methods, one hesitates to designate it as better than <u>tentative</u>, because of the relatively poor precision of the determination. The corresponding solubility at 298 K, calculated simply as (K<sub>SO</sub><sup>o</sup>)<sup>1/2</sup> would be (6.3 ± 0.7) × 10<sup>-8</sup> mol dm<sup>-3</sup> (evaluator). From the results of the individual potentiometric experiments (see compilation), it is possible to calculate the K<sub>SO</sub><sup>o</sup> = (4.0 ± 0.8) × 10<sup>-15</sup> and the corresponding <u>solubility of (6.3 ± 0.6) × 10<sup>-8</sup> mol dm<sup>-3</sup></u> (compiler). The latter values of K<sub>SO</sub><sup>o</sup> and of the solubility are preferable to the extent that no error due to conversion from the pK value was involved. Nevertheless, it would seem that a relative precision of better than 10% could perhaps be achieved for the solubility in the future.</p> <p>REFERENCES:</p> <ol style="list-style-type: none"> <li>1. EXPERIMENTAL VALUES: (continued....)

a silver indicator electrode and a  $0.01 \text{ mol dm}^{-3} \text{ AgNO}_3/\text{Ag}$  reference electrode in methanol. It was reported as  $\text{pK}_{\text{SO}}^\circ = 14.4 \pm 0.1$  ( $\text{K}_{\text{SO}}^\circ$  units are  $\text{mol}^2 \text{ dm}^{-6}$ ). Below are the results of individual experiments.

#### Exchange Experiments

(All concentrations are in  $\text{mol dm}^{-3}$ . The quantities in brackets are equilibrium concentrations).

Initial $C_{\text{NaBPh}_4}$ or $C_{\text{NaBr}}$	$10^4 [\text{NaBr}]$	$10^4 [\text{Br}^-]$	$10^2 [\text{BPh}_4^-]$	$y_{\text{BPh}_4^-}$	$y_{\text{Br}^-}$	$\frac{\text{K}_{\text{SO}}^\circ (\text{AgBPh}_4)}{\text{K}_{\text{SO}}^\circ (\text{AgBr})}$	$\text{pK}_{\text{SO}}^\circ$ (AgBPh <sub>4</sub> )
	<u>NaBPh<sub>4</sub> + AgBr</u>						
0.0030	0.37	7.0	0.86 <sub>0</sub>	0.78	0.72	12	14.4
0.0186	1.0	1.3 <sub>7</sub>	1.7 <sub>1</sub>	0.74	0.62	15	14.3
	<u>NaBr + AgBr</u>						
0.0113	0.77	12.7	1.00	0.77	0.70	8.7	14.5
0.0226	2.25	27.2	1.99	0.72	0.60	8.8	14.5

#### Potentiometric Experiments

(All concentrations and activities are in units of  $\text{mol dm}^{-3}$ )

$10^3 C_{\text{NaBPh}_4}$	E, mV	$10^{12} a_{\text{Ag}^+}$	$y_{\text{BPh}_4^-}$	$\text{K}_{\text{SO}}^\circ (\text{AgBPh}_4) \times 10^{15} / \text{mol}^2 \text{ dm}^{-6}$
1.57	-540	2.5	0.88	3.5
3.92	-552	1.6	0.83	5.2
9.80	-586	0.43	0.78	3.3

The authors report only an average value of  $\text{pK}_{\text{SO}}^\circ$ . This compiler calculates from the above data  $\text{K}_{\text{SO}}^\circ = (4.0 \pm 0.8) \times 10^{-15} \text{ mol}^2 \text{ dm}^{-6}$ . Neglecting activity corrections, the solubility is  $(6.3 \pm 0.6) \times 10^{-8} \text{ mol dm}^{-3}$  (compiler).

<p>COMPONENTS:</p> <p>(1) Silver tetraphenylborate (1-); AgC<sub>24</sub>H<sub>20</sub>B; [14637-35-5]</p> <p>(2) Tetrahydrothiophene-1,1-dioxide (sulfolane, tetramethylene sul- fone); C<sub>4</sub>H<sub>8</sub>O<sub>2</sub>S; [126-33-0]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, The City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. September 1979</p>
<p>CRITICAL EVALUATION:</p> <p>The solubility product of silver tetraphenylborate (AgBPh<sub>4</sub>) in sulfolane at 303 K was reported twice from the same laboratory (1, 2). The first determination employed UV-spectrophotometry, obtaining a formal (concentration) solubility product expressed as <math>pK_{s0} = 9.5 \pm 0.1</math> (here all <math>K_{s0}</math> values have units of <math>\text{mol}^2 \text{dm}^{-6}</math>). In the second publication (2) the determination was based on a potentiometric titration of BPh<sub>4</sub><sup>-</sup> with Ag<sup>+</sup> using a silver electrode, coupled with a calculation of activity coefficients from the Davies equation (see compilation). The new result was <math>pK_{s0} = 10.2</math>. Unfortunately, neither study mentioned the nature of temperature control and the second study did not specify how saturation was ascertained. The solubility itself might be best calculated from the concentration <math>pK_{s0}</math> of 9.5, because it is at least free of uncertainty with respect to the activity correction. Taking simply the square root of the <math>K_{s0}</math>, we obtain for the solubility: <math>(1.8 \pm 0.2) \times 10^{-5} \text{ mol dm}^{-3}</math> as the <u>tentative</u> value.</p> <p>REFERENCES:</p> <ol style="list-style-type: none"><li>1. <p>COMPONENTS:</p> <p>(1) Thallium(I) tetraphenylborate (1-); <math>\text{TlC}_{24}\text{H}_{20}\text{B}</math>; [14637-31-1]</p> <p>(2) Water; <math>\text{H}_2\text{O}</math>; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. December 1979</p>
<p>CRITICAL EVALUATION:</p> <p>The solubility of thallium(I) tetraphenylborate (<math>\text{TlBPh}_4</math>) at 298 K was reported as <math>5.29 \times 10^{-5} \text{ mol dm}^{-3}</math> in pure water (1) and as <math>1.1 \times 10^{-5} \text{ mol dm}^{-3}</math> in a THAM buffer solution (2). Both were determined by uv-spectrophotometry, but the molar absorption coefficients in the first study were characteristic of acetonitrile (not aqueous) solutions. (For a discussion of the consequences, see the critical evaluation for <math>\text{KBPh}_4</math> in aqueous systems). In the second study, the molar absorption coefficients were not specified.</p> <p>Because the ionic strength of the THAM buffer in the second study is not known, it is impossible to estimate the corresponding solubility at zero ionic strength. However, it is clear that the latter value should be lower than <math>1.1 \times 10^{-5} \text{ mol dm}^{-3}</math>, which makes for an even greater discrepancy between the two literature data. Thus, the <u>solubility of <math>5.29 \times 10^{-5} \text{ mol dm}^{-3}</math></u> reported by Pflaum and Howick (1) must be evaluated as highly <u>tentative</u>.</p> <p>REFERNECES:</p> <ol style="list-style-type: none"><li>1. <b>EXPERIMENTAL VALUES:</b> <p>The solubility product of <math>\text{TlBPh}_4</math> in N,N-dimethylformamide was reported as:</p> $pK_{\text{SO}}^{\circ} = 4.5 \text{ (} K_{\text{SO}}^{\circ} \text{ units are mol}^2 \text{ dm}^{-6}\text{)}.$ <p>The above value was derived from the electrolytic conductivity of the saturated solution <math>\kappa = 3.80 \times 10^{-4} \text{ ohm}^{-1} \text{ cm}^{-1}</math> and a mean molar activity coefficient calculated from the Guggenheim equation (not shown).</p>	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> Electrolytic conductance of the saturated solution, using apparatus previously described (1). The authors state the precision of the conductance data as $\pm 2\%$ . The value for the $\lambda^{\infty}$ of $\text{Tl}^+$ employed in the calculation was taken from the literature (2) and if the average value from the above source was used, it was $91.1 \text{ S cm}^2 \text{ mol}^{-1}$ . The $\lambda^{\infty}$ for the $\text{BPh}_4^-$ ion was estimated from the Walden rule using the known (unspecified) value in acetonitrile. Presumably, the solubility $C$ was calculated using the relationship $C = 1000\kappa/\Lambda^{\infty}$ , but this is not explained in the text and the actual solubility is not reported.	<b>SOURCE AND PURITY OF MATERIALS:</b> N,N-Dimethylformamide was purified by a literature method (3). $\text{TlBPh}_4$ was prepared as described in the compilation for dimethylsulfoxide.
<b>COMMENTS:</b> Walden's rule is known to be unreliable. The use of limiting conductivities for solutions of the order of $10^{-2} \text{ mol dm}^{-3}$ is questionable. The method of ascertaining saturation was not specified.	<b>ESTIMATED ERROR:</b> Nothing specified. <b>REFERENCES:</b> (1) Kolthoff, I. M.; Bruckenstein, S.; Chantooni, M. K., Jr. <i>J. Am. Chem. Soc.</i> <u>1961</u> , <i>83</i> , 3927. (2) Yeager, H. L.; Kratochvil, B. <i>J. Phys. Chem.</i> <u>1970</u> , <i>74</i> , 963. (3) Kolthoff, I. M.; Chantooni, M. K., Jr.; Smagowski, H. <i>Anal. Chem.</i> <u>1970</u> , <i>42</i> , 1622.

<b>COMPONENTS:</b> (1) Thallium(I) tetraphenylborate (1-); $TlC_{24}H_{20}B$ ; [14637-31-1] (2) Dimethylsulfoxide; $C_2H_6OS$ ; [67-68-5]	<b>ORIGINAL MEASUREMENTS:</b> Kolthoff, I. M.; Chantooni, M. K., Jr. <i>J. Phys. Chem.</i> <u>1972</u> , <i>76</i> , 2024-34.
<b>VARIABLES:</b> One temperature: 25°C	<b>PREPARED BY:</b> Orest Popovych
<b>EXPERIMENTAL VALUES:</b> <p>The solubility of <math>TlBPh_4</math> in dimethylsulfoxide was reported as:</p> $C = 4.9 \times 10^{-2} \text{ mol dm}^{-3}.$ <p>After determining that the above salt was completely dissociated (based on conductance data), the authors calculated the mean ionic activity coefficients from the Guggenheim equation (not shown) and reported the solubility product of <math>TlBPh_4</math> in dimethylsulfoxide as:</p> $pK_{S0}^{\circ} = 2.9 \text{ (} K_{S0}^{\circ} \text{ units are } \text{mol}^2 \text{ dm}^{-6}\text{)}.$	
<b>AUXILIARY INFORMATION</b>	
<b>METHOD/APPARATUS/PROCEDURE:</b> Electrolytic conductance of the saturated solution, using previously described apparatus (1). The electrolytic conductivity of the saturated solution at 25°C was reported as $11.5 \times 10^{-4} \text{ ohm}^{-1} \text{ cm}^{-1}$ , with a precision of $\pm 2\%$ . Values of $\Lambda^{\infty}$ in dimethylsulfoxide were estimated from those in acetonitrile using Walden's rule. Presumably, the solubility $C$ was calculated from the relationship $C = 1000\kappa/\Lambda^{\infty}$ , where $\kappa$ is the electrolytic conductivity.	<b>SOURCE AND PURITY OF MATERIALS:</b> Dimethylsulfoxide was thoroughly purified by a literature method (2). Sodium tetraphenylborate (Aldrich puriss. grade) was purified by the method of Popov and Humphrey (3). $TlBPh_4$ was prepared by metathesis of $TlNO_3$ with $NaBPh_4$ .
<b>COMMENTS:</b> Walden's rule is notoriously unreliable. In addition, errors are incurred by employing limiting conductivities at concentrations as high as the reported solubility value. The method of ascertaining saturation was not specified.	<b>ESTIMATED ERROR:</b> Nothing specified. <b>REFERENCES:</b> (1) Kolthoff, I. M.; Bruckenstein, S.; Chantooni, M. K., Jr. <i>J. Am. Chem. Soc.</i> <u>1961</u> , <i>83</i> , 3927. (2) Kolthoff, I. M.; Reddy, T. B. <i>Inorg. Chem.</i> <u>1962</u> , <i>1</i> , 189. (3) Popov, A. I.; Humphrey, R. <i>J. Am. Chem. Soc.</i> <u>1959</u> , <i>81</i> , 2043.

## COMPONENTS:

- (1) Tetraphenylarsonium tetraphenylborate (1-);  
C<sub>48</sub>H<sub>40</sub> BAs; [15627-12-0]
- (2) Water; H<sub>2</sub>O; [7732-18-5]

## EVALUATOR:

Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A.

November 1979

## CRITICAL EVALUATION:

All three reasonable estimates of the solubility of tetraphenylarsonium tetraphenylborate (Ph<sub>4</sub>As BPh<sub>4</sub>) in water come from Parker's laboratory (1-3) and all were determined at 298 K. The first two were reported as formal (concentration) solubility products (in the units of mol<sup>2</sup> dm<sup>-6</sup>) expressed in the form pK<sub>SO</sub> = 16.7 (1) and 17.2 (2), respectively. The latter value corresponds to a solubility of 2.5 x 10<sup>-9</sup> mol dm<sup>-3</sup>, but the authors' estimate of precision is ±0.5 pK units, which means that the solubility could range anywhere from 4.5 x 10<sup>-9</sup> mol dm<sup>-3</sup> to 1.4 x 10<sup>-9</sup> mol dm<sup>-3</sup>. Although the spectral region in which the saturated solutions were analyzed was not specified, the uv-determination of the solubility must have been carried out in the non-specific short-wavelength region of the near-uv spectrum, where absorption is high, but where the tetraphenyl species cannot be distinguished from other aromatics, including decomposition products. On the other hand, in the region of 260-275 nm, where tetraphenyl compounds show characteristic spectra, the molar absorption coefficients are of the order of 10<sup>3</sup> dm<sup>3</sup>(cm mol)<sup>-1</sup>, which renders impossible a uv-analysis of 10<sup>-9</sup> mol dm<sup>-3</sup> solutions. The need to analyze in the non-specific region of the spectrum may be responsible for the low precision of the reported solubility product.

Subsequently, Cox and Parker (3) expressed their preference for the determination of the solubility product by chemical-exchange experiments, between a solution of AgNO<sub>3</sub> and solid Ph<sub>4</sub>As BPh<sub>4</sub> and a solution of Ph<sub>4</sub>As NO<sub>3</sub> and solid AgBPh<sub>4</sub>. The resulting value of pK<sub>SO</sub> = 17.4 (K<sub>SO</sub> units are mol<sup>2</sup> dm<sup>-6</sup>) is difficult to assess as to precision. For one thing, it is based on the literature value for the pK<sub>SO</sub> of AgBPh<sub>4</sub> which itself is subject to an error of the order of 0.1 pK units (4). Furthermore, Cox and Parker did not mention whether or not any corrections were introduced for the activity coefficients of Ag<sup>+</sup> and Ph<sub>4</sub>As<sup>+</sup> ions in their computation. Therefore, the K<sub>SO</sub> of Ph<sub>4</sub>As BPh<sub>4</sub> is likely to be partially based on activity and partially on concentration. Since the precision in the pK<sub>SO</sub> can be no better than ±0.2 pK units, the solubility of Ph<sub>4</sub>As BPh<sub>4</sub> in water calculated as (K<sub>SO</sub>)<sup>1/2</sup> could range from about 2.5 x 10<sup>-9</sup> mol dm<sup>-3</sup> to 1.6 x 10<sup>-9</sup> mol dm<sup>-3</sup>. The nominal solubility value of 2.0 x 10<sup>-9</sup> mol dm<sup>-3</sup> should be regarded therefore as no better than tentative.

In view of the results in all three studies by Parker et al. (1-3), the K<sub>SO</sub> value of 5.0 x 10<sup>-9</sup> mol<sup>2</sup> dm<sup>-6</sup> reported by Cole and Pflaum (5) must be of the wrong order of magnitude. Since the authors did specify uv-analysis at 264 nm and 271 nm, it would appear that what they observed was absorption due to decomposition products and possibly, the starting materials.

---	---

## CRITICAL EVALUATION:

All four literature values pertaining to the solubility of tetraphenylarsonium tetraphenylborate ( $Ph_4As BPh_4$ ) in acetonitrile were determined at 298 K by Parker and his associates (1-4). All data were reported as  $pK_{s0}$  values where the  $K_{s0}$  units were  $mol^2 dm^{-6}$ . The first datum,  $pK_{s0} = 5.2$  (1) was reported with a paucity of experimental detail, except that it was a concentration solubility product determined by uv-spectrophotometry. It was superseded by another concentration solubility product, expressed as  $pK_{s0} = 5.7$  with the precision stated as  $\pm 0.1$  pK units (2). Since the experimental details were somewhat better defined in this second article, the above value may serve as the basis for calculating the solubility as  $(K_{s0})^{1/2} = (1.4 \pm 0.2) \times 10^{-3} mol dm^{-3}$ . Considering that the solubility value is precise to only one decimal and that no mention is made in the article of ascertaining saturation, this datum must be considered as only tentative.

The two later data are less reliable as sources of the solubility value. The thermodynamic ion-activity product reported as  $pK_{s0}^{\circ} = 5.8$  (3) contained an activity coefficient calculated from the Davies equation (see compilation), but the break-down between the solubility and the activity coefficient was not shown. Finally, Cox and Parker (4) expressed preference for determining the solubility product of  $Ph_4As BPh_4$  from chemical-exchange experiments, rather than by direct uv-spectrophotometry (see compilation). Unfortunately, it is not clear whether activity coefficients were used in the calculation of the solubility product, so that the reported  $pK_{s0} = 6.0$  may be a concentration or an activity product and therefore not suitable for the calculation of the solubility value. The precision of the last  $pK_{s0}$  value cannot be better than  $\pm 0.2$  pK units, considering that it is based on a literature value of the  $pK_{s0}$  ( $AgBPh_4$ ) which itself is precise to only  $\pm 0.1$  pK units.

Y. 11210, U. S. A.</p> <p>November 1979</p>
<p>CRITICAL EVALUATION:</p> <p>All three available data on the solubility of tetraphenylarsonium tetraphenylborate (<math>Ph_4As BPh_4</math>) in N,N-dimethylacetamide come from the laboratory of Parker and his associates (1-3). All were determined by uv-spectrophotometry at 298 K. The first two data were concentration solubility products (in <math>mol^2 dm^{-6}</math>) reported in the form <math>pK_{S0} = 3.4</math> (1) and 3.7 (2), respectively. Since the latter was obtained under conditions that were better defined in the article, with a specified precision of <math>\pm 0.1</math> pK units, it represents the best available quantity from which the solubility can be estimated. Thus, if the solubility is taken simply as <math>(K_{S0})^{1/2}</math>, we obtain for it <math>(1.4 \pm 0.2) \times 10^{-2} mol dm^{-3}</math>. It should be considered as a <u>tentative</u> value. The thermodynamic solubility product determined subsequently and expressed as <math>pK_{S0}^{\circ} = 4.0</math> (3) is based on an activity coefficient calculated from the Davies equation (see compilation), but unfortunately the solubility itself was not specified in that study.</p> <hr/> <p><u>References:</u></p> <ol style="list-style-type: none"> <li>1. <p>COMPONENTS:</p> <p>(1) Tetraphenylarsonium tetraphenylborate (1-); C<sub>48</sub>H<sub>40</sub>BA<sub>2</sub>; [15627-12-0]</p> <p>(2) N,N-Dimethylformamide; C<sub>3</sub>H<sub>7</sub>NO; [68-12-2]</p>	<p>EVALUATOR:</p> <p>Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A. November, 1979</p>
<p>CRITICAL EVALUATION:</p> <p>Three of the four available literature data pertaining to the solubility of tetraphenylarsonium tetraphenylborate (Ph<sub>4</sub>As BPh<sub>4</sub>) in N,N-dimethylformamide were determined at 298 K by uv-spectrophotometry in the laboratory of Parker and his associates (1-3). The first two data were concentration solubility products (in mol<sup>2</sup> dm<sup>-6</sup>) reported in the form pK<sub>g0</sub> = 3.7 (1,2), showing agreement to one decimal in the logarithm between the two studies. If we take the solubility as being equal to (K<sub>g0</sub>)<sup>1/2</sup> and accept the authors' estimate of the precision as ±0.1 pK units (2), the solubility value becomes (1.4 ± 0.2) × 10<sup>-2</sup> mol dm<sup>-3</sup>. The above value is probably the best estimate of the solubility we have to date, but it should be considered as no better than <u>tentative</u>.</p> <p>The thermodynamic solubility product reported subsequently as pK<sub>g0</sub><sup>o</sup> = 4.9 (3) is not a reliable source of the solubility value because it contains an appreciable activity correction calculated via the Davies equation (see compilation). Unfortunately, the solubility was not specified separately in the last study (3).</p> <p>The pK<sub>g0</sub><sup>o</sup> value of 3.9 reported by Kolthoff and Chantooni (4) on the basis of measurements of electrolytic conductance would seem less reliable for two reasons. Firstly, the values of molar conductances for the Ph<sub>4</sub>As<sup>+</sup> and BPh<sub>4</sub><sup>-</sup> ions required for the calculation (see compilations) were not known in N,N-dimethylformamide and had to be estimated from those in acetonitrile via Walden's rule. The latter can lead to very serious errors, however. Secondly, at the 10<sup>-2</sup> mol dm<sup>-3</sup> concentration levels, additional errors result from the use of <u>limiting</u> molar conductances. These objections pertain to the evaluation of the <u>value</u> of the solubility product. To derive the solubility from it, one would have to know the form of the Guggenheim equation used to calculate the activity coefficient, which was not specified by the authors.</p>

<p>CRITICAL EVALUATION:</p> <p>All four literature data pertaining to the solubility of tetraphenylarsonium tetraphenylborate (<math>Ph_4As BPh_4</math>) in dimethylsulfoxide are solubility products in units of <math>mol^2 dm^{-6}</math>, reported in the form of <math>pK_{S0}</math> (or <math>pK_{S0}^{\circ}</math>). All were determined at 298 K. The first two data were concentration solubility products determined by uv-spectrophotometry by Alexander and Parker and reported as <math>pK_{S0} = 3.3</math> (1) and 3.6 (2), respectively. The second value was obtained under experimental conditions that were better described in the article and was accompanied by a stated precision of <math>\pm 0.1</math> pK units. Consequently, it may represent the best source for the solubility value, which calculated as <math>(K_{S0})^{\frac{1}{2}}</math> is <math>(1.6 \pm 0.2) \times 10^{-2} mol dm^{-3}</math> (evaluator) and should be regarded as the <u>tentative</u> value.</p> <p>The thermodynamic solubility product reported subsequently as <math>pK_{S0}^{\circ} = 3.6</math> (3) was based on an activity coefficient calculated from the Davies equation (see compilation), but the break-down between the solubility and the activity correction was not shown. Considering the relatively high ionic concentration involved, the thermodynamic solubility product is not a good datum for the calculation of the solubility.</p> <p>The only independent check on the above data from another laboratory comes from Kolthoff and Chantooni (4). Unfortunately, their value expressed as <math>pK_{S0}^{\circ} = 4.3</math> is subject to too many sources of error to be reliable. Here the solubility was calculated from electrolytic conductivity <math>\kappa</math>, presumably using the relationship <math>Solubility = 1000\kappa/\Lambda^{\infty}</math>, where <math>\Lambda^{\infty}</math> is the limiting molar conductivity of the electrolyte. However, the limiting molar conductivity in dimethylsulfoxide was not known and had to be estimated from the Walden's rule, which is a highly unsatisfactory procedure. Furthermore, <u>limiting</u> molar conductivities are not anywhere near applicable to electrolyte solutions at concentrations of the order of <math>10^{-2} mol dm^{-3}</math>.</p>

<b>CRITICAL EVALUATION:</b>  All three available data on the solubility of tetraphenylarsonium tetraphenylborate ( $Ph_4As BPh_4$ ) in formamide were determined at 298 K by uv-spectrophotometry in the laboratory of Parker and his associates (1-3). The first two data were concentration solubility products (in $mol^2 dm^{-6}$ ) reported in the form $pK_{s0} = 8.3$ (1) and 8.9 (2), respectively. Since the latter was obtained under experimental conditions that were better defined in the article, with a specified precision of $\pm 0.1$ pK units, it is the best available datum from which the solubility can be estimated as $(K_{s0})^{1/2}$ . We obtain for the solubility $(3.6 \pm 0.4) \times 10^{-5} mol dm^{-3}$ as a <u>tentative</u> value. Subsequently, the thermodynamic solubility product of $Ph_4As BPh_4$ in formamide was reported in the form $pK_{s0}^{\circ} = 8.8$ (3). However, the solubility itself was not reported in the last study.  <hr/> <b>References:</b>  1. Alexander, R.; Parker, A. J. <i>J. Am. Chem. Soc.</i> <u>1967</u> , <i>89</i> , 5549. 2. Parker, A. Y. 11210, U. S. A.  November 1979
<b>CRITICAL EVALUATION:</b>  <p>All three available data on the solubility of tetraphenylarsonium tetraphenylborate (<math>Ph_4As BPh_4</math>) in hexamethylphosphorotriamide were determined at 298 K by uv-spectrophotometry in the laboratory of Parker and his associates (1-3). The first two data were concentration solubility products (in <math>mol^2 dm^{-6}</math>) reported in the form <math>pK_{s0} = 3.1</math> (1) and 3.7 (2), respectively. Since the latter was obtained under experimental conditions that were better defined in the article, with a specified precision of <math>\pm 0.1</math> pK units, it represents the best available quantity from which the solubility can be estimated. If we calculate the solubility simply as <math>(K_{s0})^{1/2}</math>, we obtain <math>(1.4 \pm 0.2) \times 10^{-2} mol dm^{-3}</math>. It should be considered as a <u>tentative</u> value. The thermodynamic solubility product reported subsequently as <math>pK_{s0}^{\circ} = 3.7</math> (3), which was calculated using an activity coefficient derived from the Davies equation (see compilation), has, surprisingly, the same numerical value as the earlier formal solubility product. Unless this is an error, it would imply that the thermodynamic solubility product was based on a new (revised) solubility value. The latter, unfortunately, was not reported.</p> <hr/> <p><u>References:</u></p> <ol style="list-style-type: none"><li>1. Alexander, R; Parker, A. J. <i>J. Am. Chem. <b>COMPONENTS:</b>  (1) Tetraphenylarsonium tetraphenylborate (1-); $C_{48}H_{40}BAs$ ; [15627-12-0]  (2) Methanol; $CH_4O$ ; [67-56-1]	<b>EVALUATOR:</b>  Orest Popovych, Department of Chemistry, City University of New York, Brooklyn College, Brooklyn, N. Y. 11210, U. S. A.  November 1979
<b>CRITICAL EVALUATION:</b>  All three determinations of the solubility of tetraphenylarsonium tetraphenylborate ( $Ph_4As BPh_4$ ) in methanol were reported from the laboratory of Parker and his associates (1-3). All results were obtained at 298 K by uv-spectrophotometry. The first two data were reported to be concentration solubility products, expressed as $pK_{s0} = 8.5$ (1) and $9.0$ (2), respectively. However, the $9.0$ value was obtained under somewhat better defined experimental conditions and had a specified precision of $\pm 0.1$ pK units. Taking the solubility as $(K_{s0})^{1/2} = (10^{-9})^{1/2}$ , we obtain for it the value $(3.2 \pm 0.4) \times 10^{-5} \text{ mol dm}^{-3}$ . Considering that temperature control was not specified and the estimate is good to only two significant figures, the above value cannot be considered as better than <u>tentative</u> .  The third datum was a thermodynamic solubility product for which the activity coefficient was calculated from the Davies equation shown in the compilation; it was expressed as $pK_{s0}^{\circ} = 9.0$ (3). Unfortunately, the value of the solubility itself was not specified in the last study.

<p>CRITICAL EVALUATION:</p> <p>There are two data pertaining to the solubility of tetraphenylarsonium tetraphenylborate (<math>Ph_4AsBPh_4</math>) in sulfolane, both determined in Parker's laboratory at 303 K (1,2). It is the first datum, the concentration solubility product in <math>mol^2 dm^{-6}</math>, expressed as <math>pK_{S0} = 5.0</math>, that provides us with the most reliable means of calculating the solubility. Taking the solubility as <math>(K_{S0})^{1/2}</math> and using the precision of <math>\pm 0.1</math> pK units as estimated by the authors, we obtain: <math>(3.2 \pm 0.4) \times 10^{-3} mol dm^{-3}</math>. Considering the lack of information on the temperature control and the fact that the solubility estimate has only two significant figures, the above value can be considered no better than <u>tentative</u>.</p> <p>The thermodynamic solubility product reported later as <math>pK_{S0}^{\circ} = 5.2</math> (2) is less reliable for calculating the solubility, as the degree of the activity correction incorporated in it is not readily known.</p>

## CRITICAL EVALUATION:

The very low solubility of tetraphenylphosphonium tetraphenylborate (Ph<sub>4</sub>P BPh<sub>4</sub>) in water would render its direct determination unreliable, and it has never been reported. However, its solubility (ion-activity) product in water was evaluated indirectly (1) using the experimentally determined solubility product of Ph<sub>4</sub>P BPh<sub>4</sub> in acetonitrile and the transfer activity coefficient of Ph<sub>4</sub>P BPh<sub>4</sub> in acetonitrile calculated from those of other electrolytes. Under the circumstances, the calculated pK<sub>S0</sub><sup>o</sup> of Ph<sub>4</sub>P BPh<sub>4</sub> in water and the solubility value derived from it represent data worthy of evaluation and application.

The above calculation made use of the fact that the transfer activity coefficient of Ph<sub>4</sub>P BPh<sub>4</sub> in acetonitrile (i.e., for the transfer from water to acetonitrile) is related to the solubility products in the two solvents as follows:

$$\log m\gamma_{\pm}^2 = pK_{S0}^o(\text{acetonitrile}) - pK_{S0}^o(\text{water}) \quad (1)$$

where  $\log m\gamma_{\pm}^2$  is the transfer activity coefficient, which in this evaluation is expressed on the weight basis (molal scale), as are the ion-activity products K<sub>S0</sub><sup>o</sup>. Since the pK<sub>S0</sub><sup>o</sup> for Ph<sub>4</sub>P BPh<sub>4</sub> in acetonitrile was reported as 5.68 ± 0.05 (1) (see compilation), the corresponding pK<sub>S0</sub><sup>o</sup> in water could be calculated from Equation 1 if the value of  $\log m\gamma_{\pm}^2$  were known. The latter was calculated from the relationship:

$$\log m\gamma_{\pm}^2(\text{Ph}_4\text{P BPh}_4) = \log m\gamma_{\pm}^2(\text{Ph}_4\text{P Pi}) + \log m\gamma_{\pm}^2(\text{KBPh}_4) - \log m\gamma_{\pm}^2(\text{KPi}) \quad (2)$$

Substituting into Equation 2 the corresponding experimentally determined values (1), where Pi is the picrate ion, we obtain:

$$\begin{aligned} \log m\gamma_{\pm}^2(\text{Ph}_4\text{P BPh}_4) &= (-6.15 \pm 0.04) + (-4.68 \pm 0.04) - (0.62 \pm 0.04) \\ &= -11.45 \pm 0.07. \end{aligned}$$

Consequently, from Equation 1:

$$pK_{S0}^o(\text{water}) = (5.68 \pm 0.05) - (-11.45 \pm 0.07) = 17.13 \pm 0.09.$$

The solubility of Ph<sub>4</sub>P BPh<sub>4</sub> in water taken simply as (K<sub>S0</sub><sup>o</sup>)<sup>1/2</sup> is therefore: (2.7 ± 0.3) × 10<sup>-9</sup> mol kg<sup>-1</sup>. Of course, the solubility value would be the same in units of mol dm<sup>-3</sup> as well. This values of the solubility and the solubility product should be considered tentative.

<b>VARIABLES:</b>  One temperature: 25.00°C	<b>PREPARED BY:</b>  Orest Popovych
<b>EXPERIMENTAL VALUES:</b>  The solubility (ion-activity) product of tetraphenylphosphonium tetraphenylborate (Ph <sub>4</sub> P BPh <sub>4</sub> ) in acetonitrile was reported as:  $pK_{S0}^{\circ} = 5.68 \text{ (} K_{S0}^{\circ} \text{ units are mol}^2 \text{ kg}^{-2}\text{)}.$ The mean molar activity coefficient was calculated using the relationship:  $-\log y_{\pm} = \frac{1.64 C^{1/2}}{1 + 0.485 a C^{1/2}}$ where C was the solubility in mol dm <sup>-3</sup> and $\bar{a}$ , the mean ion-size parameter. Although the article states that an ion size of 0.5 nm was adopted for the tetraphenyl ions, this is an error. According to the calculations in the research notebook of A. Gibofsky (1), the magnitude of $\bar{a}$ used in the calculations was 0.82 nm. The actual values for the solubility and the activity coefficient were not published, but they were 1.262 x 10 <sup>-3</sup> mol dm <sup>-3</sup> and $y_{\pm} = 0.889$ , respectively (1). The resulting $pK_{S0}^{\circ} = 5.90$ ( $K_{S0}^{\circ}$ units of mol <sup>2</sup> dm <sup>-6</sup> ). The published value of $pK_{S0}^{\circ} = 5.68$ was calculated from the above using the density of acetonitrile, 0.777 g cm <sup>-3</sup> .

## SYSTEM INDEX

Underlined page numbers refer to evaluation text and those not underlined to compiled tables. All compounds, except tetraphenylborates are listed as in Chemical Abstract indexes. For example, toluene is listed as benzene, methyl-, and dimethylsulfoxide is listed as methane, sulfinylbis-. The second and subsequent components of ternary and multicomponent systems are given as molecular formulae rather than chemical name. In this volume only tetraphenylborates are listed under their IUPAC name.
