NOTICE TO READERS

Dear Reader

If your library is not already a standing-order customer or subscriber to the Solubility Data Series, may we recommend that you place a standing order or subscription order to receive immediately upon publication all new volumes published in this valuable series. Should you find that these volumes no longer serve your needs, your order can be cancelled at any time without notice.

IN MEMORIAM

Dr. Paolo Franzosini, Professor of Physical Chemistry, University of Pavia, Italy, and the Editor of this volume, passed away on January 24, 1986 at the age of 56.

Born in Trecate, near Turin, he received his university education while on a prestigious scholarship at the Collegio Ghislieri of the University of Pavia, graduating with honors in 1952. He then spent two years as a post-doctoral research assistant with Professor Clusius in the Department of Physical Chemistry at the Federal Polytechnic Institute of Zurich. In the years 1955-1960 he served as Assistant Professor at the University of Pavia, and had been promoted to the rank of Associate Professor at the early age of thirty. In 1965 he moved to the University of Camerino as Professor and Chair of Physical Chemistry. In 1968 he was back at his alma mater as Professor of Electrochemistry, and in 1980 as the Chair of Physical Chemistry. In 1979 he served as Visiting Professor at the University of Mogadiscio, Somaliland, and in 1981 at the University of Michigan in Ann Arbor.

In the thirty years of scientific activity, he published over 100 papers, mostly in the field of thermodynamics and thermochemistry of molten salt systems. He made significant contribution to the Atlas of Miscibility Gaps in 1968, and to the Atlas of Phase Diagrams in 1973 on molten salts with organic anions. In 1980 he coedited, with Professor Sanesi, Volume 28 of IUPAC's Chemical Data Series on Thermodynamics and Transport Properties of Organic Salts. In the years 1978-1984 he was member of IUPAC Commission on Thermodynamics. In 1982 he joined the Solubility Data Project and served as the National Representative of Italy to IUPAC's Commission on Solubility Data. At that time he was appointed Editor of the present volume.

He has not seen the completion of this volume. Thanks to the devotion and expertise of his colleagues, Professors Ferloni, Schiraldi and Spinolo of the Department of Physical Chemistry, University of Pavia, this volume, the final major work of Professor Franzosini, was brought to completion.

Paolo was an interesting intellect with a broad European humanitarian culture. He was a Rotarian from an early age, president of the Rotary Club of Pavia, and served in the distinguished position of Rotary District Governor in 1982-3.

Through the generosity of the Franzosini family, it has been possible for the Solubility Data Commission to establish the Paolo Franzosini Endowment Fund, the proceeds of which to assist young scientists in their association with IUPAC's Solubility Data Project.

We are all diminished by his passing.

FOREWORD

*If the knowledge is
undigested or simply wrong,
more is not better*

How to communicate and disseminate numerical data effectively in chemical science and technology has been a problem of serious and growing concern to IUPAC, the International Union of Pure and Applied Chemistry, for the last two decades. The steadily expanding volume of numerical information, the formulation of new interdisciplinary areas in which chemistry is a partner, and the links between these and existing traditional subdisciplines in chemistry, along with an increasing number of users, have been considered as urgent aspects of the information problem in general, and of the numerical data problem in particular.

Among the several numerical data projects initiated and operated by various IUPAC commissions, the *Solubility Data Project* is probably one of the most ambitious ones. It is concerned with preparing a comprehensive critical compilation of data on solubilities in all physical systems, of gases, liquids and solids. Both the basic and applied branches of almost all scientific disciplines require a knowledge of solubilities as a function of solvent, temperature and pressure. Solubility data are basic to the fundamental understanding of processes relevant to agronomy, biology, chemistry, geology and oceanography, medicine and pharmacology, and metallurgy and materials science. Knowledge of solubility is very frequently of great importance to such diverse practical applications as drug dosage and drug solubility in biological fluids, anesthesiology, corrosion by dissolution of metals, properties of glasses, ceramics, concretes and coatings, phase relations in the formation of minerals and alloys, the deposits of minerals and radioactive fission products from ocean waters, the composition of ground waters, and the requirements of oxygen and other gases in life support systems.

The widespread relevance of solubility data to many branches and disciplines of science, medicine, technology and engineering, and the difficulty of recovering solubility data from the literature, lead to the proliferation of published data in an ever increasing number of scientific and technical primary sources. The sheer volume of data has overcome the capacity of the classical secondary and tertiary services to respond effectively.

While the proportion of secondary services of the review article type is generally increasing due to the rapid growth of all forms of primary literature, the review articles become more limited in scope, more specialized. The disturbing phenomenon is that in some disciplines, certainly in chemistry, authors are reluctant to treat even those limited-in-scope reviews exhaustively. There is a trend to preselect the literature, sometimes under the pretext of reducing it to manageable size. The crucial problem with such preselection - as far as numerical data are concerned - is that there is no indication as to whether the material was excluded by design or by a less than thorough literature search. We are equally concerned that most current secondary sources, critical in character as they may be, give scant attention to numerical data.

On the other hand, tertiary sources - handbooks, reference books and other tabulated and graphical compilations - as they exist today are comprehensive but, as a rule, uncritical. They usually attempt to cover whole disciplines, and thus obviously are superficial in treatment. Since they command a wide market, we believe that their service to the advancement of science is at least questionable. Additionally, the change which is taking place in the generation of new and diversified numerical data, and the rate at which this is done, is not reflected in an increased third-level service. The emergence of new tertiary literature sources does not parallel the shift that has occurred in the primary literature.

With the status of current secondary and tertiary services being as briefly stated above, the innovative approach of the Solubility Data Project is that its compilation and critical evaluation work involve consolidation and reprocessing services when both activities are based on intellectual and scholarly reworking of information from primary sources. It comprises compact compilation, rationalization and simplification, and the fitting of isolated numerical data into a critically evaluated general framework.

The Solubility Data Project has developed a mechanism which involves a number of innovations in exploiting the literature fully, and which contains new elements of a more imaginative approach for transfer of reliable information from primary to secondary/tertiary sources. *The fundamental trend of the Solubility Data Project is toward integration of secondary and tertiary services with the objective of producing in-depth critical analysis and evaluation which are characteristic to secondary services, in a scope as broad as conventional tertiary services.*

Fundamental to the philosophy of the project is the recognition that the basic element of strength is the active participation of career scientists in it. Consolidating primary data, producing a truly critically-evaluated set of numerical data, and synthesizing data in a meaningful relationship are demands considered worthy of the efforts of top scientists. Career scientists, who themselves contribute to science by their involvement in active scientific research, are the backbone of the project. The scholarly work is commissioned to recognized authorities, involving a process of careful selection in the best tradition of IUPAC. This selection in turn is the key to the quality of the output. These top experts are expected to view their specific topics dispassionately, paying equal attention to their own contributions and to those of their peers. They digest literature data into a coherent story by weeding out what is wrong from what is believed to be right. To fulfill this task, the evaluator must cover all relevant open literature. No reference is excluded by design and every effort is made to detect every bit of relevant primary source. Poor quality or wrong data are mentioned and explicitly disqualified as such. In fact, it is only when the reliable data are presented alongside the unreliable data that proper justice can be done. The user is bound to have incomparably more confidence in a succinct evaluative commentary and a comprehensive review with a complete bibliography to both good and poor data.

It is the standard practice that the treatment of any given solute-solvent system consists of two essential parts: I. Critical Evaluation and Recommended Values, and II. Compiled Data Sheets.

The Critical Evaluation part gives the following information:

- (i) a verbal text of evaluation which discusses the numerical solubility information appearing in the primary sources located in the literature. The evaluation text concerns primarily the quality of data after consideration of the purity of the materials and their characterization, the experimental method employed and the uncertainties in control of physical parameters, the reproducibility of the data, the agreement of the worker's results on accepted test systems with standard values, and finally, the fitting of data, with suitable statistical tests, to mathematical functions;
- (ii) a set of recommended numerical data. Whenever possible, the set of recommended data includes weighted average and standard deviations, and a set of smoothing equations derived from the experimental data endorsed by the evaluator;
- (iii) a graphical plot of recommended data.

The Compilation part consists of data sheets of the best experimental data in the primary literature. Generally speaking, such independent data sheets are given only to the best and endorsed data covering the known range of experimental parameters. Data sheets based on primary sources where the data are of a lower precision are given only when no better data are available. Experimental data with a precision poorer than considered acceptable are reproduced in the form of data sheets when they are the only known data for a particular system. Such data are considered to be still suitable for some applications, and their presence in the compilation should alert researchers to areas that need more work.

The typical data sheet carries the following information:

- (i) components - definition of the system - their names, formulas and Chemical Abstracts registry numbers;
- (ii) reference to the primary source where the numerical information is reported. In cases when the primary source is a less common periodical or a report document, published though of limited availability, abstract references are also given;
- (iii) experimental variables;
- (iv) identification of the compiler;
- (v) experimental values as they appear in the primary source. Whenever available, the data may be given both in tabular and graphical form. If auxiliary information is available, the experimental data are converted also to SI units by the compiler.

Under the general heading of Auxiliary Information, the essential experimental details are summarized:

- (vi) experimental method used for the generation of data;
- (vii) type of apparatus and procedure employed;
- (viii) source and purity of materials;
- (ix) estimated error;
- (x) references relevant to the generation of experimental data as cited in the primary source.

This new approach to numerical data presentation, formulated at the initiation of the project and perfected as experience has accumulated, has been strongly influenced by the diversity of background of those whom we are supposed to serve. We thus deemed it right to preface the evaluation/compilation sheets in each volume with a detailed discussion of the principles of the accurate determination of relevant solubility data and related thermodynamic information.

Finally, the role of education is more than corollary to the efforts we are seeking. The scientific standards advocated here are necessary to strengthen science and technology, and should be regarded as a major effort in the training and formation of the next generation of scientists and engineers. Specifically, we believe that there is going to be an impact of our project on scientific-communication practices. The quality of consolidation adopted by this program offers down-to-earth guidelines, concrete examples which are bound to make primary publication services more responsive than ever before to the needs of users. The self-regulatory message to scientists of the early 1970s to refrain from unnecessary publication has not achieved much. A good fraction of the literature is still cluttered with poor-quality articles. The Weinberg report (in 'Reader in Science Information', ed. J. Sherrod and A. Hodina, Microcard Editions Books, Indian Head, Inc., 1973, p. 292) states that 'admonition to authors to restrain themselves from premature, unnecessary publication can have little effect unless the climate of the entire technical and scholarly community encourages restraint...' We think that projects of this kind translate the climate into operational terms by exerting pressure on authors to avoid submitting low-grade material. The type of our output, we hope, will encourage attention to quality as authors will increasingly realize that their work will not be suited for permanent retrievability unless it meets the standards adopted in this project. It should help to dispel confusion in the minds of many authors of what represents a permanently useful bit of information of an archival value, and what does not.

If we succeed in that aim, even partially, we have then done our share in protecting the scientific community from unwanted and irrelevant, wrong numerical information.

A. S. Kertes

PREFACE

1. Phase relationships of alkali alkanoates.

1.1. Solid state transitions of alkali alkanoates.

Most alkali alkanoates (either linear or branched) exhibit polymorphism in the solid state, and the number of phases tends to increase with increasing chain length. However, controversy often exists about the number, nature, and stability range of the polymorphs present in a given salt. Since different hydrates appear as well, "in the literature one may find almost the whole Greek alphabet, primed and unprimed, each notation supposed to define a separate phase. It has been maintained that each such phase is associated with a unique crystal structure, while others have claimed that the different X-ray diffraction patterns do not necessarily represent true crystal structures, but instead are merely associated with different types of disorder of the chains. There is also the additional problem of the descendant phases, i.e., structures that occur at some elevated temperature and remain unaltered at room temperature in a pseudoequilibrium for a long time" (Ref. 1). The present volume discusses solubilities of those linear alkali alkanoates marked with a cross in the scheme below, and, as well, the iso-butanoates and iso-pentanoates of Na and K. No information is available so far on the solubilities of other alkali alkanoates.

In order to obtain a homogeneous picture of the thermal behavior (in terms of phase transformation temperatures and enthalpy changes) of alkali alkanoates, more than 100 linear and branched homologues belonging to the different alkali families have been submitted to DSC analysis during the last few years in the editor's laboratory. The results obtained on heating are thought to offer an acceptable degree of trustworthiness and internal consistency. Therefore, as useful background material for discussion of the solubility curves, the pertinent superambient solid state transition temperature, T_{trs}, are collected in Tables 1 and 2. These temperatures represent first order, or predominantly first order, phase transitions. For completeness, the temperatures of fusion, T_{fus}, and of clearing, T_{clr}, (when they exist) are also listed in Tables 1 and 2. However, the data on sodium octadecanoate (produced in a different laboratory) are listed separately in Table 4.

The following remarks can be made about the precision and accuracy of the data reported in Tables 1, 2.

Precision is not infrequently better than ±1 K, although becoming poorer in some cases: in particular, very poor reproducibility was obtained for solid state transitions of sodium methanoate and ethanoate.

Accuracy is thought to be often of the same order of magnitude as precision. However, one must consider that DSC is a dynamic method of investigation, and that some solid state transitions of methanoates and ethanoates are characterized (even on heating at a moderate scanning rate) by a remarkable sluggishness. Consequently, in Tables 1, 2 the T_{trs} data for the shortest homologues can be somewhat too high. This disadvantage tends

to decrease in the next higher homologues, and does not involve fusion and clearing. As an example, high accuracy equilibrium adiabatic calorimetric data, taken very recently by Franzosini et al. (Refs. 8, 9) on sodium methanoate and propanoate, are compared in Table 3 with the previous DSC values. The comparison also includes the enthalpy changes involved.

For sodium octadecanoate, reference will be made to the recent DSC data by Forster et al. (Ref. 10), collected in Table 4.

1.2. Mesomorphism in alkali alkanooates.

Mesomorphic phases (liquid crystalline, or plastic crystalline, or both) can also form in alkali alkanooates, the stability range of the mesomorphic state being intermediate between those of the "true" crystalline and of the "true" liquid phases. In particular, liquid crystals (likely of the smectic type) form in linear alkanooates, starting with butanoate when the cation is either sodium or potassium, from pentanoate when the cation is rubidium, and from hexanoate when the cation is caesium. No liquid crystals form when the cation is lithium. In long chain homologues (which, however, are of little relevance to the present purposes) plastic crystals form for all alkali cations. (See, e.g., the data reported in Table 4 for sodium octadecanoate.)

Unfortunately, the nomenclature employed by different authors is far from homogeneous. In particular, most Russian investigators call "fusion" the transformation of either a crystalline solid or a liquid crystal into an isotropic liquid which is often misleading in the interpretation of phase diagrams. More reasonably, in non - Russian literature a distinction is usually made between clearing temperature, T_{clr} (i.e., the temperature at which a liquid crystal transforms into an isotropic liquid), and fusion temperature, T_{fus} (i.e., the temperature at which a "true" crystal transforms into either an isotropic liquid or a liquid crystal)(*). Further details on these points are given in Section 2.2.

(*) It might be further considered whether in the sequence (met in several long chain alkali alkanooates): crystal \rightarrow plastic crystal(s) \rightarrow liquid crystal(s) \rightarrow isotropic liquid the term "fusion" should be applied to the first or to the second transformation, but such a discussion would be of little relevance here. In Table 4 the term fusion was applied to the transformation from the (plastic crystalline) subneat to the (liquid crystalline) neat I phase.

The literature contains reports on the phase diagrams of 58 binaries (9 with common anion, and 49 with common cation), involving alkali alkanates which exhibit mesomorphism: they are listed in Table 5 where the component(s) which can exist in the mesomorphic liquid state are underlined.

Unfortunately, information is mostly restricted to the lower boundary of the isotropic liquid field. More details are available only in a limited number of cases among which special interest is to be attached to the following: a) $(C_4H_7O_2)K + (C_4H_7O_2)Na$, b) $(C_4H_7O_2)Li + (C_4H_7O_2)Na$, c) $KC_2H_3O_2 + KC_4H_7O_2$, d) $NaC_2H_3O_2 + NaC_4H_7O_2$, and e) $NaC_4H_7O_2 + NaNO_3$, inasmuch as a comparison is here possible between the results obtained by Prisyazhnyi et al. (Refs. 11, 12), who studied the lower boundaries of both the isotropic liquid and the liquid crystal fields, and those obtained by previous authors, who studied only the lower boundary of the isotropic liquid.

Table 5 - Binaries involving at least one alkali alkanate able to exist in the liquid crystalline state.

\sim Compounds which form liquid crystals.

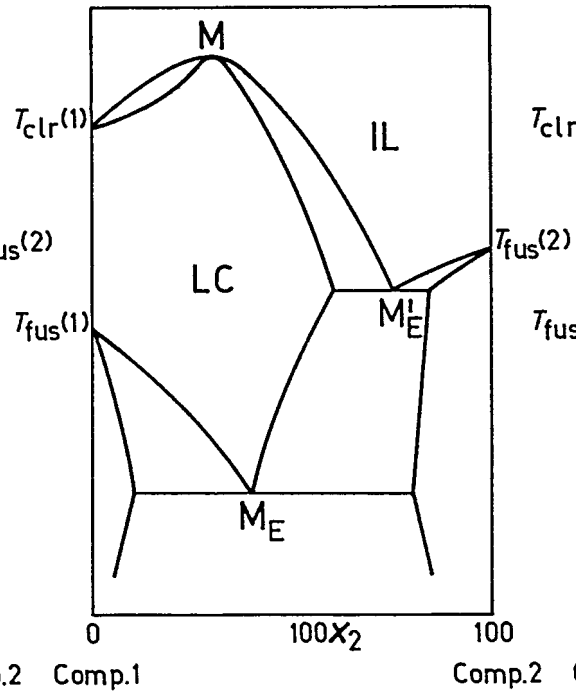

In order to improve homogeneity and succinctness in discussing the systems in Table 5, it seemed convenient to present here a selection of model phase diagrams [see Schemes A, ..., D (*)] to which reference will be made in the subsequent critical evaluations.

(*) Schemes A, ..., D were drawn in the - usually accepted - assumption that any (actually known) transformation mesomorphic phase \leftrightarrow isotropic liquid is first order.

SCHEME C.1

SCHEME C.2

SCHEME C.3

SCHEME D.1

SCHEME D.2

SCHEME D.3

It must be noted that in these diagrams the presence of liquid crystals causes the occurrence of invariants to which no official designation has been given so far. Therefore, in order to avoid misunderstandings, throughout the present volume we indicate (provisionally) as M_E an invariant at which liquid crystals, LC (and not an isotropic liquid, IL, as in a common eutectic, E), are in equilibrium with two solids; and, respectively, as M'_E an invariant at which an isotropic liquid is in equilibrium with the liquid crystals and one solid phase (and not with two solid phases, as in a common eutectic, E). Here the subscript E is added because the situation of the equilibrium curves involved is similar to that met at a eutectic point.

For situations similar to those met in Schemes B, the subscript P will be used.

By analogy, invariants (met in subsequent Schemes) involving equilibria among two liquid crystalline and one isotropic liquid phase will be indicated as M''_E and M''_P , respectively. Finally, invariants involving two liquid crystalline and one solid phase (i.e., exhibiting a situation similar to that met in a monotectic) will be designated as M_M points.

Scheme A.1.

Component 1 can exist as a liquid crystal between $T_{fus}(1)$ and $T_{clr}(1)$. Component 2 melts at $T_{fus}(2)$, and actually cannot exist as a liquid crystal. Components 1, 2 are assumed to be partially miscible in the solid state (*). The binary invariants are an M_E and an M'_E point.

Scheme A.2.

This differs from Scheme A.1 in that a maximum, M, is present in the liquid crystal - isotropic liquid equilibrium curves.

Scheme A.3.

This differs from Scheme A.1 in that complete mutual solubility (with a minimum, m) is assumed for components 1, 2 in the solid state.

Scheme B.1.

This differs from Scheme A.1 in that the isotropic liquid - liquid crystal equilibrium curves impinge on the liquidus branch richer in component 1. Accordingly the binary invariants are a eutectic, E, and an M'_p point.

Schemes B.2, B.3.

These represent self-explanatory modifications of Scheme B.1.

Scheme C.1.

Both components can exist as liquid crystals between $T_{fus}(1)$ and $T_{clr}(1)$, and between $T_{fus}(2)$ and $T_{clr}(2)$, respectively. Mutual solubility is assumed to be complete in the mesomorphic liquid, and limited in the solid state. The only binary invariant is an M_E point.

Scheme C.2.

This differs from Scheme C.1 in that a limited mutual solubility is assumed for the components in the liquid crystalline state. Besides the M_E point, two more binary invariants exist, i.e., an M_E and an M_M point.

Scheme C.3.

This is a special case (Ref. 13) where four liquid crystal - isotropic liquid diphasic fields ought to be formed, with one maximum, M, and two minima, m_1 and m_2 , respectively.

Scheme D.1.

Component 1 can exist as a liquid crystal between $T_{fus}(1)$ and $T_{clr}(1)$. Component 2 melts at $T_{fus}(2)$, and cannot exist as a liquid crystal. An intermediate compound $[(1)_2(2)_3]$ in the Scheme; D: dystectic point] is formed, which cannot exist as a liquid crystal. The binary invariants are E, M_E , M'_E .

(*) Indeed, the complete absence of mutual solubility in the solid state has to be considered an exception rather than the rule.

Scheme D.2.

This differs from Scheme D.1 in that liquid crystal formation is assumed for both components.

Scheme D.3.

This differs from Scheme D.1 in that the intermediate compound melts yielding a liquid crystalline and an isotropic liquid phase; consequently, an M_p point is formed.

Detailed information (updated 1979) on the phase relationships of alkanooates are given in Chapter 1.2 (Ref. 14) of a volume on thermodynamic and transport properties of organic salts published (1980) as a book project of the IUPAC Commission on Thermodynamics.

2. Some ambiguities met in the current literature.

2.1. Transition and peritectic points in binary systems.

Breaks along a branch of the lower boundary of the isotropic liquid region in a binary (where, for simplicity it is assumed that no mesomorphic phases are involved) can arise from the occurrence of

- (a) polymorphic (first order) transformations in either component (examples are shown in Schemes E.1 - E.3);
 - (b) limited mutual solubility of the components in the solid state (an example is shown in Scheme F);
 - (c) incongruent fusion of an intermediate compound (an example is shown in Scheme G).
- (i) In Schemes E.1 - E.3 component 1 undergoes (at constant pressure) the polymorphic (first order) transformation

In Scheme E.1, it is further assumed that component 2 (in the solid state) is soluble in neither polymorph of component 1.

At $T = T_{trs}(1)$, equilibrium exists among solid polymorphs $(1)_I$ and $(1)_{II}$, and the isotropic liquid of composition x_T :

Scheme E.2 shows one of the possible situations which can be met when it is assumed that component 2 is soluble only in one polymorph of component 1 [in Scheme E.2: in polymorph $(1)_{II}$ stable at $T \leq T_{trs}(1)$]. At $T_p \neq T_{trs}(1)$ [in Scheme E.2: $T_p > T_{trs}(1)$], equilibrium exists (at constant pressure) among solid polymorph $(1)_I$, solid solutions S [of composition x_S , and formed with polymorph $(1)_{II}$ and component 2], and isotropic liquid of composition x_p :

Scheme E.3 shows one of the possible situations which can be met when it is assumed that component 2 is soluble in either polymorph of component 1. At T_p , the phases in invariant equilibrium (at constant pressure) are: the isotropic liquid of composition x_p , and two solid solutions of composition $x_{S\beta}$ and $x_{S\alpha}$, respectively.

In Schemes E, the isotropic liquid of composition either x_T (Scheme E.1), or x_p (Schemes E.2, E.3) is incongruent with respect to the two solid coexisting phases (i.e., the liquid cannot be synthesized from the solids). When in a binary the incongruent liquid is in equilibrium (at constant pressure) with two solids of the same composition [i.e., in Scheme E.1: polymorphs $(1)_I$ and $(1)_{II}$] the point representing the liquid phase (in Scheme E.1: point T, whose abscissa is x_T) is designated as a transition point.

When in a binary the incongruent liquid is in equilibrium (at constant pressure) with two solids of different composition, Haase and Schoenert (Ref. 15) call the point representing the liquid phase (i.e., in Schemes E.2 and E.3: point P, whose abscissa is x_p) a peritectic point. Haase and Schönert's definition of peritectic

SCHEME E.1

SCHEME E.2

SCHEME E.3

SCHEME F

SCHEME G

point is convenient for the present purposes, but less restrictive than other widely used formulations. A detailed discussion is unnecessary here, but if any other formulations are accepted, the various situations should be considered accordingly.

- (ii) In Scheme F, components 1 and 2 are assumed to exhibit a limited mutual solubility in the solid state. At the peritectic point, P, the equilibrium is:

- (iii) Finally, in Scheme G, the intermediate compound [(1)₂(2)], in the specific case] is said to melt incongruently at T_p because (at this temperature) the isotropic liquid, (IL)_p, is once more incongruent with respect to both solid phases [i.e., (1)₂(2) and (1)] entering the peritectic equilibrium

In this case, the invariant, P, is designated either a peritectic point, or transition point of the peritectic type (Ref. 15).

- (iv) The situations shown in Schemes E-G, though apparently far different from one another, can be distinguished only with difficulty in the absence of information on the solidus, e.g., on the phase relations of the pure components, the Tammann triangles (examples of which are shown in Scheme G), etc. Unfortunately, a number of authors, who restricted their investigations to the visual polythermal determination of the liquidus, were frequently inclined either to assume a break on a liquidus branch as an evidence for the existence of an incongruently melting compound (correct only in Scheme G), or to identify the temperature at which a break occurs with that at which a pure component undergoes a phase transition (correct only in Scheme E.1).

As a final remark, it can be added that in the Russian literature an invariant point P is indicated only occasionally as a "peritekticheskaya tochka" (i.e., peritectic point), but most often as a "perekhodnaya tochka" which, however, is translated in English issues of the Russian journals as either transition point (a correct, though rather misleading, literal translation), or peritectic point, etc.

2.2. The case of pure components.

This subject was already mentioned in Section 1.2, but it is now thought useful to comment further on one or two specific papers.

(i) Sokolov, in one of his earliest studies (1954; Ref. 16) on alkanooates, reported that crystalline sodium methanoate, ethanoate, and propanoate melted directly into isotropic liquids, whereas several other sodium alkanooates behaved "as if they had two distinct fusion temperatures: the first one relevant to the transformation from the solid crystalline to the liquid crystalline phase, and the second one to that from the liquid crystalline to the isotropic liquid phase"(*). This statement was in agreement with previous findings by a few former authors known to him; see, e.g., Ref. 17.

Despite the correctness of the above assertions, Sokolov then decided unfortunately (Ref. 16) "to assume as the fusion temperature ... of both the pure salts and mixtures thereof the temperature at which the homogeneity of the melt disappeared"(*) (which, however, is correct only in the absence of mesomorphic phases).

This decision caused a misinterpretation of the topology of several among the many systems studied later on by the Smolensk group, as will be seen throughout the volume.

(ii) In 1956 Sokolov (Ref. 18) provided information, during the 10th Scientific Conference of the Smolensk Medical Institute, on phase transformations occurring in several alkali alkanooates at $T < T_{fus}$. Here fusion is obviously to be intended in Sokolov's sense, i.e., either true fusion or clearing. This information - which concerned only temperatures, and not the nature of the transformations - appeared in the Summaries of Papers presented at the Conference. Sokolov's summary could not be directly consulted but, as far as we know, no numerical data were reported on it. None the less, it has been subsequently quoted by the investigators of the Smolensk group as the pertinent primary source. Comparison of such quotations, however, shows inconsistencies,

* Translated from Russian by P. Ferloni, Pavia (Italy).

a few of which are:

- (a) There should be either three transitions of sodium propanoate (at 468, 490, and 560 K, respectively) according to Ref. 19, or four (at 350, 468, 490, and 560 K, respectively) according to Ref. 20.
- (b) There should be either two transitions of potassium n-butanoate (at 463, and 553-558 K, respectively) according to Ref. 21, or three (at 463, 553-558, and 618 K, respectively) according to Ref. 22.
- (c) There should be either two transitions of potassium iso-pentanoate (at 327, and 618 K, respectively) according to Refs. 21, 23, or three (at 473, 493, and 618 K, respectively) according to Ref. 24.

(iii) Because divergent opinions have been expressed rather frequently by different authors about the number, nature, and location of phase transformations occurring in alkanates, each single situation has been critically evaluated throughout the volume. No discussion, on the contrary, has been made of the phase transformations occurring in the inorganic components of the systems, inasmuch as data from various sources proved usually to be either coincident or negligibly different.

3. Tabulation of the systems.

Binaries with common anion have been listed in Part 1 of the volume following the increasing complexity of the anion, and, for a given anion, following the alphabetical order of the cation.

Example:

Component 1	Component 2
$(\text{CHO}_2)_2\text{Ba}$	$(\text{CHO}_2)_2\text{K}_2$
$(\text{CHO}_2)_2\text{Ba}$	$(\text{CHO}_2)_2\text{Na}_2$
...	...
$(\text{CHO}_2)_2\text{Ca}$	$(\text{CHO}_2)_2\text{K}_2$
...	...
$(\text{CHO}_2)\text{K}$	$(\text{CHO}_2)\text{Li}$
...	...
$(\text{C}_2\text{H}_3\text{O}_2)_2\text{Cd}$	$(\text{C}_2\text{H}_3\text{O}_2)\text{Cs}$
Etc.	Etc.

Binaries with common cation have been listed in Part 2 of the volume following the alphabetical order of the cation, and, for a given cation, following the self-explanatory scheme reported here.

Component 1	Component 2
...	...
KBr	KCHO ₂
KBr	KC ₂ H ₃ O ₂
...	...
KCHO ₂	KC ₃ H ₅ O ₂
KCHO ₂	KC ₄ H ₇ O ₂
KCHO ₂	K1-C ₄ H ₇ O ₂
KCHO ₂	KCl
Etc.	Etc.

INTRODUCTION TO THE SOLUBILITY OF SOLIDS IN LIQUIDS

Nature of the Project

The Solubility Data Project (SDP) has as its aim a comprehensive search of the literature for solubilities of gases, liquids, and solids in liquids or solids. Data of suitable precision are compiled on data sheets in a uniform format. The data for each system are evaluated, and where data from different sources agree sufficiently, recommended values are proposed. The evaluation sheets, recommended values, and compiled data sheets are published on consecutive pages.

Definitions

A mixture (1, 2) describes a gaseous, liquid, or solid phase containing more than one substance, when the substances are all treated in the same way.

A solution (1, 2) describes a liquid or solid phase containing more than one substance, when for convenience one of the substances, which is called the solvent, and may itself be a mixture, is treated differently than the other substances, which are called solutes. If the sum of the mole fractions of the solutes is small compared to unity, the solution is called a dilute solution.

The solubility of a substance B is the relative proportion of B (or a substance related chemically to B) in a mixture which is saturated with respect to solid B at a specified temperature and pressure. Saturated implies the existence of equilibrium with respect to the processes of dissolution and precipitation; the equilibrium may be stable or metastable. The solubility of a substance in metastable equilibrium is usually greater than that of the corresponding substance in stable equilibrium. (Strictly speaking, it is the activity of the substance in metastable equilibrium that is greater.) Care must be taken to distinguish true metastability from supersaturation, where equilibrium does not exist.

Either point of view, mixture or solution, may be taken in describing solubility. The two points of view find their expression in the quantities used as measures of solubility and in the reference states used for definition of activities, activity coefficients and osmotic coefficients.

The qualifying phrase "substance related chemically to B" requires comment. The composition of the saturated mixture (or solution) can be described in terms of any suitable set of thermodynamic components. Thus, the solubility of a salt hydrate in water is usually given as the relative proportion of anhydrous salt in solution, rather than the relative proportions of hydrated salt and water.

Quantities Used as Measures of Solubility

1. Mole fraction of substance B, x_B :

$$x_B = n_B / \sum_{s=1}^c n_s \quad [1]$$

where n_s is the amount of substance of s , and c is the number of distinct substances present (often the number of thermodynamic components in the system). Mole per cent of B is $100 x_B$.

2. Mass fraction of substance B, w_B :

$$w_B = m_B' / \sum_{s=1}^c m_s' \quad [2]$$

where m_s' is the mass of substance s . Mass per cent is $100 w_B$. The equivalent terms weight fraction and weight per cent are not used.

3. Solute mole (mass) fraction of solute B (3, 4):

$$x_{s,B} = m_B / \sum_{s=1}^{c'} m_s = x_B / \sum_{s=1}^{c'} x_s \quad [3]$$

$$w_{s,B} = m_B' / \sum_{s=1}^{c'} m_s' = w_B / \sum_{s=1}^{c'} w_s \quad [3a]$$

where the summation is over the solutes only. For the solvent A, $x_{S,A} = x_A/(1 - x_A)$, $w_{S,A} = w_A/(1 - w_A)$. These quantities are called Jänecke mole (mass) fractions in many papers.

4. Molality of solute B (1, 2) in a solvent A:

$$m_B = n_B/n_A M_A \quad \text{SI base units: mol kg}^{-1} \quad [4]$$

where M_A is the molar mass of the solvent.

5. Concentration of solute B (1, 2) in a solution of volume V:

$$c_B = [B] = n_B/V \quad \text{SI base units: mol m}^{-3} \quad [5]$$

The symbol c_B is preferred to $[B]$, but both are used. The terms molarity and molar are not used.

Mole and mass fractions are appropriate to either the mixture or the solution point of view. The other quantities are appropriate to the solution point of view only. Conversions among these quantities can be carried out using the equations given in Table I-1 following this Introduction. Other useful quantities will be defined in the prefaces to individual volumes or on specific data sheets.

In addition to the quantities defined above, the following are useful in conversions between concentrations and other quantities.

6. Density: $\rho = m/V$ SI base units: kg m^{-3} [6]

7. Relative density: d ; the ratio of the density of a mixture to the density of a reference substance under conditions which must be specified for both (1). The symbol d_t will be used for the density of a mixture at $t^\circ\text{C}$, 1 bar divided by the density of water at $t^\circ\text{C}$, 1 bar. (In some cases 1 atm = 101.325 kPa is used instead of 1 bar = 100 kPa.)

8. A note on nomenclature. The above definitions use the nomenclature of the IUPAC Green Book (1), in which a solute is called B and a solvent A. In compilations and evaluations, the first-named component (component 1) is the solute, and the second (component 2 for a two-component system) is the solvent. The reader should bear these distinctions in nomenclature in mind when comparing nomenclature and theoretical equations given in this Introduction with equations and nomenclature used on the evaluation and compilation sheets.

Thermodynamics of Solubility

The principal aims of the Solubility Data Project are the tabulation and evaluation of: (a) solubilities as defined above; (b) the nature of the saturating phase. Thermodynamic analysis of solubility phenomena has two aims: (a) to provide a rational basis for the construction of functions to represent solubility data; (b) to enable thermodynamic quantities to be extracted from solubility data. Both these are difficult to achieve in many cases because of a lack of experimental or theoretical information concerning activity coefficients. Where thermodynamic quantities can be found, they are not evaluated critically, since this task would involve critical evaluation of a large body of data that is not directly relevant to solubility. The following is an outline of the principal thermodynamic relations encountered in discussions of solubility. For more extensive discussions and references, see books on thermodynamics, e.g., (5-12).

Activity Coefficients (1)

(a) Mixtures. The activity coefficient f_B of a substance B is given by

$$RT \ln (f_B x_B) = \mu_B - \mu_B^* \quad [7]$$

where μ_B^* is the chemical potential of pure B at the same temperature and pressure. For any substance B in the mixture,

$$\lim_{x_B \rightarrow 1} f_B = 1 \quad [8]$$

(b) Solutions.

(1) Solute B. The molal activity coefficient γ_B is given by

$$RT \ln (\gamma_B m_B) = \mu_B - (\mu_B - RT \ln m_B)^\infty \quad [9]$$

where the superscript ∞ indicates an infinitely dilute solution. For any solute B,

$$\gamma_B^\infty = 1 \quad [10]$$

Activity coefficients γ_B connected with concentrations c_B , and $f_{x,B}$ (called the rational activity coefficient) connected with mole fractions x_B are defined in analogous ways. The relations among them are (1, 9), where ρ^* is the density of the pure solvent:

$$f_B = (1 + M_A \sum_S m_S) \gamma_B = [\rho + \sum_S (M_A - M_S) c_S] \gamma_B / \rho^* \quad [11]$$

$$\gamma_B = (1 - \sum_S x_S) f_{x,B} = (\rho - \sum_S M_S c_S) \gamma_B / \rho^* \quad [12]$$

$$\gamma_B = \rho^* f_{x,B} [1 + \sum_S (M_S / M_A - 1) x_S] / \rho = \rho^* (1 + \sum_S m_S) \gamma_B / \rho \quad [13]$$

For an electrolyte solute $B \equiv C_{\nu+} A_{\nu-}$, the activity on the molality scale is replaced by (9)

$$\gamma_B m_B = \gamma_{\pm}^{\nu} m_B^{\nu} Q^{\nu} \quad [14]$$

where $\nu = \nu_+ + \nu_-$, $Q = (\nu_+^{\nu_+} \nu_-^{\nu_-})^{1/\nu}$, and γ_{\pm} is the mean ionic activity coefficient on the molality scale. A similar relation holds for the concentration activity, γ_{BCB} . For the mole fractional activity,

$$f_{x,B} x_B = Q^{\nu} f_{\pm}^{\nu} x_{\pm}^{\nu} \quad [15]$$

where $x_{\pm} = (x_+ x_-)^{1/\nu}$. The quantities x_+ and x_- are the ionic mole fractions (9), which are

$$x_+ = \nu_+ x_B / [1 + \sum_S (\nu_S - 1) x_S]; \quad x_- = \nu_- x_B / [1 + \sum_S (\nu_S - 1) x_S] \quad [16]$$

where ν_S is the sum of the stoichiometric coefficients for the ions in a salt with mole fraction x_S . Note that the mole fraction of solvent is now

$$x_A^* = (1 - \sum_S \nu_S x_S) / [1 + \sum_S (\nu_S - 1) x_S] \quad [17]$$

so that

$$x_A^* + \sum_S \nu_S x_S = 1 \quad [18]$$

The relations among the various mean ionic activity coefficients are:

$$f_{\pm} = (1 + M_A \sum_S \nu_S m_S) \gamma_{\pm} = [\rho + \sum_S (\nu_S M_A - M_S) c_S] \gamma_{\pm} / \rho^* \quad [19]$$

$$\gamma_{\pm} = \frac{(1 - \sum_S x_S) f_{\pm}}{1 + \sum_S (\nu_S - 1) x_S} = (\rho - \sum_S M_S c_S) \gamma_{\pm} / \rho^* \quad [20]$$

$$\gamma_{\pm} = \frac{\rho^* [1 + \sum_S (M_S / M_A - 1) x_S] f_{\pm}}{\rho [1 + \sum_S (\nu_S - 1) x_S]} = \rho^* (1 + \sum_S m_S) \gamma_{\pm} / \rho \quad [21]$$

(11) Solvent, A:

The osmotic coefficient, ϕ , of a solvent A is defined as (1):

$$\phi = (\mu_A^* - \mu_A) / RT M_A \sum_S m_S \quad [22]$$

where μ_A^* is the chemical potential of the pure solvent.

The rational osmotic coefficient, ϕ_x , is defined as (1):

$$\phi_x = (\mu_A - \mu_A^*) / RT \ln x_A = \phi M_A \sum_S m_S / \ln(1 + M_A \sum_S m_S) \quad [23]$$

The activity, a_A , or the activity coefficient, f_A , is sometimes used for the solvent rather than the osmotic coefficient. The activity coefficient is defined relative to pure A, just as for a mixture.

For a mixed solvent, the molar mass in the above equations is replaced by the average molar mass; i.e., for a two-component solvent with components J, K, M_A becomes

$$M_A = M_J + (M_K - M_J) x_{v,K} \quad [24]$$

where $x_{v,K}$ is the solvent mole fraction of component K.

The osmotic coefficient is related directly to the vapor pressure, p , of a solution in equilibrium with vapor containing A only by (12, p.306):

$$\phi M_A \sum_S \nu_S m_S = - \ln(p/p_A^*) + (V_{m,A}^* - B_{AA})(p - p_A^*) / RT \quad [25]$$

where p_A^* , $V_{m,A}^*$ are the vapor pressure and molar volume of pure solvent A, and B_{AA} is the second virial coefficient of the vapor.

The Liquid Phase

A general thermodynamic differential equation which gives solubility as a function of temperature, pressure and composition can be derived. The approach is similar to that of Kirkwood and Oppenheim (7); see also (11, 12). Consider a solid mixture containing c thermodynamic components

1. The Gibbs-Duhem equation for this mixture is:

$$\sum_{i=1}^c x_i' (S_i' dT - V_i' dp + d\mu_i') = 0 \quad [26]$$

A liquid mixture in equilibrium with this solid phase contains c' thermodynamic components 1, where $c' > c$. The Gibbs-Duhem equation for the liquid mixture is:

$$\sum_{i=1}^c x_i (S_i dT - V_i dp + d\mu_i) + \sum_{i=c+1}^{c'} x_i (S_i dT - V_i dp + d\mu_i) = 0 \quad [27]$$

Subtract [26] from [27] and use the equation

$$d\mu_i = (d\mu_i)_{T,p} - S_i dT + V_i dp \quad [28]$$

and the Gibbs-Duhem equation at constant temperature and pressure:

$$\sum_{i=1}^c x_i (d\mu_i)_{T,p} + \sum_{i=c+1}^{c'} x_i (d\mu_i)_{T,p} = 0 \quad [29]$$

The resulting equation is:

$$RT \sum_{i=1}^c x_i' (d \ln a_i)_{T,p} = \sum_{i=1}^c x_i' (H_i - H_i') dT/T - \sum_{i=1}^c x_i' (V_i - V_i') dp \quad [30]$$

where

$$H_i - H_i' = T(S_i - S_i') \quad [31]$$

is the enthalpy of transfer of component 1 from the solid to the liquid phase at a given temperature, pressure and composition, with H_i and S_i the partial molar enthalpy and entropy of component 1.

Use of the equations

$$H_i - H_i^0 = -RT^2 (\partial \ln a_i / \partial T)_{x,p} \quad [32]$$

and

$$V_i - V_i^0 = RT (\partial \ln a_i / \partial p)_{x,T} \quad [33]$$

where superscript 0 indicates an arbitrary reference state gives:

$$RT \sum_{i=1}^c x_i' d \ln a_i = \sum_{i=1}^c x_i' (H_i^0 - H_i') dT/T - \sum_{i=1}^c x_i' (V_i^0 - V_i') dp \quad [34]$$

where

$$d \ln a_i = (d \ln a_i)_{T,p} + (\partial \ln a_i / \partial T)_{x,p} dT + (\partial \ln a_i / \partial p)_{x,T} dp \quad [35]$$

The terms involving enthalpies and volumes in the solid phase can be written as:

$$\sum_{i=1}^c x_i' H_i' = H_s^* \quad \sum_{i=1}^c x_i' V_i' = V_s^* \quad [36]$$

With eqn [36], the final general solubility equation may then be written:

$$RT \sum_{i=1}^c x_i' d \ln a_i = (H_s^* - \sum_{i=1}^c x_i' H_i^0) d(1/T) - (V_s^* - \sum_{i=1}^c x_i' V_i^0) dp/T \quad [37]$$

Note that those components which are not present in both phases do not appear in the solubility equation. However, they do affect the solubility through their effect on the activities of the solutes.

Several applications of eqn [37] (all with pressure held constant) will be discussed below. Other cases will be discussed in individual evaluations.

(a) Solubility as a function of temperature.

Consider a binary solid compound $A_n B$ in a single solvent A. There is

no fundamental thermodynamic distinction between a binary compound of A and B which dissociates completely or partially on melting and a solid mixture of A and B; the binary compound can be regarded as a solid mixture of constant composition. Thus, with $c = 2$, $x_A = n/(n+1)$, $x_B = 1/(n+1)$, eqn [37] becomes:

$$d \ln(a_A^n a_B) = -\Delta H_{AB}^0 d(1/RT) \quad [38]$$

where

$$\Delta H_{AB}^0 = nH_A + H_B - (n+1)H_S^* \quad [39]$$

is the molar enthalpy of melting and dissociation of pure solid A_nB to form A and B in their reference states. Integration between T and T_0 , the melting point of the pure binary compound A_nB , gives:

$$\ln(a_A^n a_B) = \ln(a_A^n a_B)_{T=T_0} - \int_{T_0}^T \Delta H_{AB}^0 d(1/RT) \quad [40]$$

(i) Non-electrolytes

In eqn [32], introduce the pure liquids as reference states. Then, using a simple first-order dependence of ΔH_{AB}^* on temperature, and assuming that the activity coefficients conform to those for a simple mixture (6):

$$RT \ln f_A = wx_B^2 \quad RT \ln f_B = wx_A^2 \quad [41]$$

then, if w is independent of temperature, eqn [32] and [33] give:

$$\ln(x_B(1-x_B)^n) + \ln\left[\frac{n^n}{(1+n)^{n+1}}\right] = G(T) \quad [42]$$

where

$$G(T) = - \left[\frac{\Delta H_{AB}^* - T^* \Delta C_p^*}{R} \right] \left[\frac{1}{T} - \frac{1}{T^*} \right] + \frac{\Delta C_p^*}{R} \ln(T/T^*) - \frac{w}{R} \left[\frac{x_A^2 + nx_B^2}{T} - \frac{n}{(n+1)T^*} \right] \quad [43]$$

where ΔC_p^* is the change in molar heat capacity accompanying fusion plus decomposition of the pure compound to pure liquid A and B at temperature T^* , (assumed here to be independent of temperature and composition), and ΔH_{AB}^* is the corresponding change in enthalpy at $T - T^*$. Equation [42] has the general form:

$$\ln\{x_B(1-x_B)^n\} = A_1 + A_2/(T/K) + A_3 \ln(T/K) + A_4(x_A^2 + nx_B^2)/(T/K) \quad [44]$$

If the solid contains only component B, then $n = 0$ in eqn [42] to [44].

If the infinite dilution reference state is used, then:

$$RT \ln f_{x,B} = w(x_A^2 - 1) \quad [45]$$

and [39] becomes

$$\Delta H_{AB}^\infty = nH_A^* + H_B^\infty - (n+1)H_S^* \quad [46]$$

where ΔH_{AB}^∞ is the enthalpy of melting and dissociation of solid compound A_nB to the infinitely dilute reference state of solute B in solvent A; H_A^* and H_B^∞ are the partial molar enthalpies of the solute and solvent at infinite dilution. Clearly, the integral of eqn [32] will have the same form as eqn [35], with ΔH_{AB}^∞ replacing ΔH_{AB}^* , ΔC_p^∞ replacing ΔC_p^* , and $x_A^2 - 1$ replacing x_A^2 in the last term.

See (5) and (11) for applications of these equations to experimental data.

(ii) Electrolytes

(a) Mole fraction scale

If the liquid phase is an aqueous electrolyte solution, and the solid is a salt hydrate, the above treatment needs slight modification. Using rational mean activity coefficients, eqn [34] becomes:

$$\ln \left\{ \frac{x_B^{\nu} (1 - x_B)^n}{[1 + (\nu - 1)x_B]^{n+\nu}} \right\} - \ln \left\{ \frac{n^n}{(n + \nu)^{n+\nu}} \right\} + \ln \left\{ \left[\frac{f_{B^*}}{T_{B^*}} \right]^{\nu} \left[\frac{f_{A^*}}{T_{A^*}} \right]^n \right\} \quad [47]$$

$$- - \left[\frac{\Delta H_{AB}^* - T^* \Delta C_p^*}{R} \right] \left\{ \frac{1}{T} - \frac{1}{T^*} \right\} + \frac{\Delta C_p^*}{R} \ln(T/T^*)$$

where superscript * indicates the pure salt hydrate. If it is assumed that the activity coefficients follow the same temperature dependence as the right-hand side of eqn [47] (13-16), the thermochemical quantities on the right-hand side of eqn [47] are not rigorous thermodynamic enthalpies and heat capacities, but are apparent quantities only. Data on activity coefficients (9) in concentrated solutions indicate that the terms involving these quantities are not negligible, and their dependence on temperature and composition along the solubility-temperature curve is a subject of current research.

A similar equation (with $\nu = 2$ and without the heat capacity terms or activity coefficients) has been used to fit solubility data for some MOH-H₂O systems, where M is an alkali metal (13); enthalpy values obtained agreed well with known values. The full equation has been deduced by another method in (14) and applied to MCl₂-H₂O systems in (14) and (15). For a summary of the use of equation [47] and similar equations, see (14).

(2) Molality scale

Substitution of the mean activities on the molality scale in eqn [40] gives:

$$\nu \ln \left[\frac{\gamma_{\pm} m_B}{\gamma_{\pm}^* m_B^*} \right] - \nu (m_B/m_B^* - 1) - \nu (m_B(\phi - 1)/m_B^* - \phi^* + 1) \quad [48]$$

$$= G(T)$$

where $G(T)$ is the same as in eqn [47], $m_B^* = 1/nM_A$ is the molality of the anhydrous salt in the pure salt hydrate and γ_{\pm} and ϕ are the mean activity coefficient and the osmotic coefficient, respectively. Use of the osmotic coefficient for the activity of the solvent leads, therefore, to an equation that has a different appearance to [47]; the content is identical. However, while eqn [47] can be used over the whole range of composition ($0 \leq x_B \leq 1$), the molality in eqn [48] becomes infinite at $x_B = 1$; use of eqn [48] is therefore confined to solutions sufficiently dilute that the molality is a useful measure of composition. The essentials of eqn [48] were deduced by Williamson (17); however, the form used here appears first in the *Solubility Data Series*. For typical applications (where activity and osmotic coefficients are not considered explicitly, so that the enthalpies and heat capacities are apparent values, as explained above), see (18).

The above analysis shows clearly that a rational thermodynamic basis exists for functional representation of solubility-temperature curves in two-component systems, but may be difficult to apply because of lack of experimental or theoretical knowledge of activity coefficients and partial molar enthalpies. Other phenomena which are related ultimately to the stoichiometric activity coefficients and which complicate interpretation include ion pairing, formation of complex ions, and hydrolysis. Similar considerations hold for the variation of solubility with pressure, except that the effects are relatively smaller at the pressures used in many investigations of solubility (5).

(b) Solubility as a function of composition.

At constant temperature and pressure, the chemical potential of a saturating solid phase is constant:

$$\mu_{A_n B^*} = \mu_{A_n B}(\text{sln}) = n\mu_A + \mu_B \quad [49]$$

$$= (n\mu_A^{\infty} + \nu_+ \mu_+^{\infty} + \nu_- \mu_-^{\infty}) + nRT \ln f_{A_n} x_A$$

$$+ \nu RT \ln(\gamma_{\pm} m_{\pm} Q)$$

for a salt hydrate $A_n B$ which dissociates to water (A), and a salt (B), one mole of which ionizes to give ν_+ cations and ν_- anions in a solution in which other substances (ionized or not) may be present. If the saturated solution is sufficiently dilute, $f_A = x_A = 1$, and the quantity K_s in

$$\Delta G^{\infty} = (\nu_+ \mu_+^{\infty} + \nu_- \mu_-^{\infty} + n\mu_A^* - \mu_{AB}^*)$$

$$= -RT \ln K_s$$

$$= -\nu RT \ln(Q\gamma_{\pm}m_B) \quad [50]$$

is called the solubility product of the salt. (It should be noted that it is not customary to extend this definition to hydrated salts, but there is no reason why they should be excluded.) Values of the solubility product are often given on mole fraction or concentration scales. In dilute solutions, the theoretical behaviour of the activity coefficients as a function of ionic strength is often sufficiently well known that reliable extrapolations to infinite dilution can be made, and values of K_S can be determined. In more concentrated solutions, the same problems with activity coefficients that were outlined in the section on variation of solubility with temperature still occur. If these complications do not arise, the solubility of a hydrate salt $C_{\nu}A_{\nu} \cdot nH_2O$ in the presence of other solutes is given by eqn [50] as

$$\nu \ln\{m_B/m_B(0)\} = -\nu \ln\{\gamma_{\pm}/\gamma_{\pm}(0)\} - n \ln\{a_A/a_A(0)\} \quad [51]$$

where a_A is the activity of water in the saturated solution, m_B is the molality of the salt in the saturated solution, and (0) indicates absence of other solutes. Similar considerations hold for non-electrolytes.

Consideration of complex mixed ligand equilibria in the solution phase are also frequently of importance in the interpretation of solubility equilibria. For nomenclature connected with these equilibria (and solubility equilibria as well), see (19, 20).

The Solid Phase

The definition of solubility permits the occurrence of a single solid phase which may be a pure anhydrous compound, a salt hydrate, a non-stoichiometric compound, or a solid mixture (or solid solution, or "mixed crystals"), and may be stable or metastable. As well, any number of solid phases consistent with the requirements of the phase rule may be present. Metastable solid phases are of widespread occurrence, and may appear as polymorphic (or allotropic) forms or crystal solvates whose rate of transition to more stable forms is very slow. Surface heterogeneity may also give rise to metastability, either when one solid precipitates on the surface of another, or if the size of the solid particles is sufficiently small that surface effects become important. In either case, the solid is not in stable equilibrium with the solution. See (21) for the modern formulation of the effect of particle size on solubility. The stability of a solid may also be affected by the atmosphere in which the system is equilibrated.

Many of these phenomena require very careful, and often prolonged, equilibration for their investigation and elimination. A very general analytical method, the "wet residues" method of Schreinemakers (22), is often used to investigate the composition of solid phases in equilibrium with salt solutions. This method has been reviewed in (23), where [see also (24)] least-squares methods for evaluating the composition of the solid phase from wet residue data (or initial composition data) and solubilities are described. In principle, the same method can be used with systems of other types. Many other techniques for examination of solids, in particular X-ray, optical, and thermal analysis methods, are used in conjunction with chemical analyses (including the wet residues method).

COMPILATIONS AND EVALUATIONS

The formats for the compilations and critical evaluations have been standardized for all volumes. A brief description of the data sheets has been given in the FOREWORD; additional explanation is given below.

Guide to the Compilations

The format used for the compilations is, for the most part, self-explanatory. The details presented below are those which are not found in the FOREWORD or which are not self-evident.

Components. Each component is listed according to IUPAC name, formula, and Chemical Abstracts (CA) Registry Number. The formula is given either in terms of the IUPAC or Hill (25) system and the choice of formula is governed by what is usual for most current users: i.e., IUPAC for inorganic compounds, and Hill system for organic compounds. Components are ordered according to:

- (a) saturating components;
- (b) non-saturating components in alphanumerical order;
- (c) solvents in alphanumerical order.

The saturating components are arranged in order according to a 18-column periodic table with two additional rows:

- Columns 1 and 2: H, alkali elements, ammonium, alkaline earth elements
- 3 to 12: transition elements
- 13 to 17: boron, carbon, nitrogen groups; chalcogenides, halogens
- 18: noble gases
- Row 1: Ce to Lu
- Row 2: Th to the end of the known elements, in order of atomic number.

Salt hydrates are generally not considered to be saturating components since most solubilities are expressed in terms of the anhydrous salt. The existence of hydrates or solvates is carefully noted in the text, and CA Registry Numbers are given where available, usually in the critical evaluation. Mineralogical names are also quoted, along with their CA Registry Numbers, again usually in the critical evaluation.

Original Measurements. References are abbreviated in the forms given by Chemical Abstracts Service Source Index (CASSI). Names originally in other than Roman alphabets are given as transliterated by Chemical Abstracts.

Experimental Values. Data are reported in the units used in the original publication, with the exception that modern names for units and quantities are used; e.g., mass per cent for weight per cent; mol dm⁻³ for molar; etc. Both mass and molar values are given. Usually, only one type of value (e.g., mass per cent) is found in the original paper, and the compiler has added the other type of value (e.g., mole per cent) from computer calculations based on 1983 atomic weights (26).

Errors in calculations and fitting equations in original papers have been noted and corrected, by computer calculations where necessary.

Method. Source and Purity of Materials. Abbreviations used in Chemical Abstracts are often used here to save space.

Estimated Error. If these data were omitted by the original authors, and if relevant information is available, the compilers have attempted to estimate errors from the internal consistency of data and type of apparatus used. Methods used by the compilers for estimating and reporting errors are based on the papers by Ku and Eisenhart (27).

Comments and/or Additional Data. Many compilations include this section which provides short comments relevant to the general nature of the work or additional experimental and thermodynamic data which are judged by the compiler to be of value to the reader.

References. See the above description for Original Measurements.

Guide to the Evaluations

The evaluator's task is to check whether the compiled data are correct, to assess the reliability and quality of the data, to estimate errors where necessary, and to recommend "best" values. The evaluation takes the form of a summary in which all the data supplied by the compiler have been critically reviewed. A brief description of the evaluation sheets is given below.

Components. See the description for the Compilations.

Evaluator. Name and date up to which the literature was checked.

Critical Evaluation

(a) **Critical text.** The evaluator produces text evaluating all the published data for each given system. Thus, in this section the evaluator reviews the merits or shortcomings of the various data. Only published data are considered; even published data can be considered only if the experimental data permit an assessment of reliability.

(b) **Fitting equations.** If the use of a smoothing equation is justifiable the evaluator may provide an equation representing the solubility as a function of the variables reported on all the compilation sheets.

(c) **Graphical summary.** In addition to (b) above, graphical summaries are often given.

(d) **Recommended values.** Data are recommended if the results of at least two independent groups are available and they are in good agreement, and if the evaluator has no doubt as to the adequacy and reliability of the applied experimental and computational procedures. Data are considered as tentative if only one set of measurements is

available, or if the evaluator considers some aspect of the computational or experimental method as mildly undesirable but estimates that it should cause only minor errors. Data are considered as doubtful if the evaluator considers some aspect of the computational or experimental method as undesirable but still considers the data to have some value in those instances where the order of magnitude of the solubility is needed. Data determined by an inadequate method or under ill-defined conditions are rejected. However references to these data are included in the evaluation together with a comment by the evaluator as to the reason for their rejection.

(e) References. All pertinent references are given here. References to those data which, by virtue of their poor precision, have been rejected and not compiled are also listed in this section.

(f) Units. While the original data may be reported in the units used by the investigators, the final recommended values are reported in S.I. units (1, 28) when the data can be accurately converted.

<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 0.1 K (compiler).</p>	

<p>COMPONENTS:</p> <p>(1) Potassium methanoate (potassium formate); (CHO₂)K; [590-29-4]</p> <p>(2) Lithium methanoate (lithium formate); (CHO₂)Li; [556-63-8]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied by Sokolov and Tsindrik (Ref. 1) as a side of the reciprocal ternary K, Li/CHO₂, NO₃, and by Pochtakova (Ref. 2) as a side of the ternary CHO₂/K, Li, Na. In both cases, the visual polythermal analysis was employed, and the investigation was restricted to the liquidus.</p> <p>The obtained results, i.e., formation of a 1:1 congruently melting intermediate compound giving a eutectic with either component, are qualitatively similar. It is, however, to be remarked that no explanation is offered by Pochtakova (Ref. 2, where Ref. 1 is quoted) for the considerable difference between the temperature she found (427 K) for the eutectic at 100x₁ about 40, and that (413 K) measured previously by Sokolov and Tsindrik (Ref. 1).</p> <p>The fusion temperatures of the pure components reported in both Ref. 1 and Ref. 2, i.e., T_{fus}(1)= 440 K, T_{fus}(2)= 546 K, are in fair agreement with those listed in Table 1 of the Preface (441.9±0.5 K, 546±1 K). On the contrary, poor correspondence exists between solid state transition temperatures quoted in Ref. 1 from Ref. 3 (i.e., 333, 408, and 430 K for component 1; 360, 388, and 505 for component 2) and those listed in Table 1 of the Preface (418±1 K for component 1, and 496±2 K for component 2).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Tsindrik, N.M. COMPONENTS: (1) Potassium methanoate (potassium formate); $(\text{CHO}_2)_2\text{K}$; [590-29-4] (2) Magnesium methanoate (magnesium formate) $(\text{CHO}_2)_2\text{Mg}$; [557-39-1]	EVALUATOR: Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).
CRITICAL EVALUATION: <p>The system was studied by Berchiesi et al. (Ref. 1), who indicated component 1 as $(\text{CHO}_2)_2\text{K}_2$, and by Pochtakova (Ref. 2), who indicated component 1 as $(\text{CHO}_2)_2\text{K}$ in Table 6 of her paper, and as $(\text{CHO}_2)_2\text{K}_2$ in Fig. 2. Inspection of text and figures led both the compiler and evaluator to assume the latter formula as the correct one: consequently, a direct comparison is possible between data from either sources.</p> <p>Comparison makes apparent that Pochtakova (Ref. 2), who seems not to be aware of Ref. 1, could obtain no evidence for the eutectic due to the fact that she performed no measurements at $0 < 100x_2 \leq 5$, while the eutectic composition (Ref. 1) is $100x_2 = 1.3$.</p> <p>It is to be added that: (i) Berchiesi et al.'s fusion temperature of component 1 read by the evaluator on the original plot, i.e., $T_{\text{fus}}(1) \sim 169^\circ\text{C}$ (442 K) agrees with the value $T_{\text{fus}}(1) = 441.9 \pm 0.5$ K reported in Table 1 of the Preface more satisfactorily than Pochtakova's figure (440 K); (ii) the solid state transition temperatures quoted for component 1 in Ref. 2 from Ref. 3 (i.e., 333, 408, and 430 K) cannot be identified with the relevant data of Table 1 of the Preface, where a single transition is mentioned which occurs at $T_{\text{trs}}(1)/\text{K} = 418 \pm 1$; and (iii) Pochtakova's points are affected by a scattering noticeably larger than Berchiesi et al.'s.</p> <p>In conclusion, the evaluator recommends the data by Berchiesi et al. (Ref. 1), although regretting that they are presented only in graphical form, and not supported by any investigation of the solidus.</p> <p>REFERENCES:</p> <p>(1) Berchiesi, G.; Cingolani, A.; Leonesi, D.; Piantoni, G. <i>Can. <p>COMPONENTS:</p> <p>(1) Potassium methanoate (potassium formate); (CHO₂)K; [590-29-4]</p> <p>(2) Sodium methanoate (sodium formate); (CHO₂)Na; [141-53-7]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>																											
<p>CRITICAL EVALUATION:</p>																												
<p>The binary CHO₂/K, Na was studied by Dmitrevskaya (as a side system of the reciprocal ternary CHO₂, NO₃/K, Na; Ref. 1) and by Leonesi et al. (as a side system of the reciprocal ternary CHO₂, Cl/K, Na; Ref. 2). In both papers, visual observation was employed, and investigation was restricted to the liquidus; moreover, the latter authors listed only the few numerical data which were relevant to their purposes.</p>																												
<p>The main features of the phase diagrams given in either source exhibit rather close similarities, as shown here:</p>																												
<table border="1"> <thead> <tr> <th></th> <th>Ref. 1</th> <th>Ref. 2</th> </tr> </thead> <tbody> <tr> <td>T_{fus}(1)/K:</td> <td>440</td> <td>441.9</td> </tr> <tr> <td>T_{fus}(2)/K:</td> <td>531</td> <td>530.7</td> </tr> <tr> <td>Intermediate compound (i.c.)</td> <td>(CHO₂)₄K₃Na</td> <td>(CHO₂)₄K₃Na</td> </tr> <tr> <td>T_{fus}(i.c.)/K:</td> <td>-</td> <td>453.2</td> </tr> <tr> <td>Eutectic E₁; T/K:</td> <td>441</td> <td>438.2</td> </tr> <tr> <td>Eutectic E₁; x₂:</td> <td>0.505</td> <td>0.495</td> </tr> <tr> <td>Eutectic E₂; T/K:</td> <td>440</td> <td>436.7</td> </tr> <tr> <td>Eutectic E₂; x₂:</td> <td>0.04</td> <td>0.043</td> </tr> </tbody> </table>		Ref. 1	Ref. 2	T _{fus} (1)/K:	440	441.9	T _{fus} (2)/K:	531	530.7	Intermediate compound (i.c.) T _{fus} (i.c.)/K:	-	453.2																										
Eutectic E ₁ ; T/K:	441	438.2																										
Eutectic E ₁ ; x ₂ :	0.505	0.495																										
Eutectic E ₂ ; T/K:	440	436.7																										
Eutectic E ₂ ; x ₂ :	0.04	0.043																										
<p>It is, however, to be stressed that: (i) Dmitrevskaya's liquidus branch rich in component 1 exhibits a maximum (unexplained by the author) at 444 K and x₁ = 0.98, whereas Leonesi et al. found a monotonically decreasing trend; and (ii) Dmitrevskaya quotes (from Ref. 3) the occurrence of phase transitions in component 1 (at 333, 408, and 430 K), and in component 2 (at 515 K) which have no correspondence in Table 1 of the Preface.</p>																												
<p>Due to these reasons, and to the higher accuracy to be attributed to the findings by Leonesi et al., the evaluator is inclined to recommend the data listed above under the heading "Ref. 2".</p>																												
<p>It is finally to be added that previous cryometric work had allowed Leonesi et al. (Ref. 4) to infer, on the basis of the well known equation</p>																												
$\lim_{m \rightarrow 0} \frac{(\Delta T/m)}{K} = 1 - \rho_0$																												
<p>(K: cryometric constant of component 1, used as the solvent; ΔT: experimental freezing point depression; m: molality of component 2, used as the solute), a limiting value ρ₀ about 0.17 for the ratio between the solute concentrations in the solid and liquid phases at equilibrium.</p>

AUXILIARY INFORMATION																																																							
METHOD/APPARATUS/PROCEDURE: Visual polythermal method; temperatures measured with a Nichrome-Constantane thermocouple.	SOURCE AND PURITY OF MATERIALS: Materials of analytical purity recrystallized twice (extrapolated $t_{\text{fus}}/^\circ\text{C}$ of lithium methanoate: 273; author).																																																						
NOTE: The fusion temperatures of both components, $T_{\text{fus}}(1) = 546 \text{ K}$ and $T_{\text{fus}}(2) = 531 \text{ K}$, are in excellent agreement with the corresponding values listed in Table 1 of the Preface. The abscissa of point m, $100x_2 = 50$, coincides with that found by Pochtakova (Ref. 1), whereas its ordinate, 443 K, is somewhat lower than Pochtakova's value, i.e., 449 K.	ESTIMATED ERROR: Temperature: accuracy probably $\pm 2 \text{ K}$ (compiler). REFERENCES: (1) Pochtakova, E.I. Zh. Neorg. Khim. <u>1980</u> , 25, 1147-1150; Russ. J. Inorg. Chem. (Engl. Transl.) <u>1980</u> , 25, 637-639 (*).

AUXILIARY INFORMATION																																								
METHOD/APPARATUS/PROCEDURE: Visual polythermal method.	SOURCE AND PURITY OF MATERIALS: Materials prepared by reacting the proper ("chemically pure") carbonate with a slight excess of methanoic acid of analytical purity (Ref. 1). Component 1 undergoes a phase transition at $t_{\text{trs}}(1)/^\circ\text{C} = 140$. Component 2 undergoes a phase transition at $t_{\text{trs}}(2)/^\circ\text{C} = 242$ (Ref. 2).																																							
NOTE: Concerning component 2, it can be remarked that the fusion temperature given by the author, $T_{\text{fus}}(2) = 531$ K, is in excellent agreement with the value listed in Table 1 of the Preface, i.e., 530.7 ± 0.5 K, whereas the value quoted from Ref. 2 for the solid state transition temperature, $T_{\text{trs}}(2) = 515$ K, is noticeably higher than that reported in the Table, i.e., 502 ± 5 K. It can be added that Berchiesi et al. (Ref. 3) asserted they could not investigate this binary due to thermal instability of the mixtures of any composition.	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).

AUXILIARY INFORMATION																																											
METHOD/APPARATUS/PROCEDURE: Visual polythermal method; temperatures measured with a Chromel-Alumel thermocouple and a PP potentiometer. Additional investigations were performed by means of thermographical analysis, electrical conductometry, and X-ray diffractometry.	SOURCE AND PURITY OF MATERIALS: Not stated.																																										
NOTE: The occurrence of the intermediate compound is supported by X-ray diffractometry, and seems reliable. According to the authors, this compound has a density of 2.472 g cm^{-3} . Although the $T_{fus}(2)$ value (454 K) given in this paper is lower than the corresponding one from Table 1 of the Preface, i.e., 463 K, the general trend of the phase diagram should be considered as substantially correct.	ESTIMATED ERROR: Temperature: accuracy probably $\pm 2 \text{ K}$ (compiler). REFERENCES:																																										

<p>COMPONENTS:</p> <p>(1) Cadmium ethanoate (cadmium acetate); ($C_2H_3O_2$)₂Cd; [543-90-8]</p> <p>(2) Potassium ethanoate (potassium acetate); ($C_2H_3O_2$)K; [127-08-2]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied by Lehrman and Schweitzer (Ref. 1), Il'yasov (Ref. 2), Pavlov and Golubkova (Ref. 3), and Nadirov and Bakeev (Ref. 4), with significantly discrepant results.</p> <p>Lehrman and Schweitzer (Ref. 1), and Pavlov and Goblubkova (Ref. 3) claim the existence of three congruently melting intermediate compounds, and four eutectics; however, both the coordinates of the eutectics, and the compositions and the fusion temperatures of the intermediate compounds given in either paper do not allow one to reconcile the phase diagram proposed in Ref. 1 with that reported in Ref. 3.</p> <p>According to Il'yasov (Ref. 2), a single eutectic should exist [at 505 K (232 °C) and 100x₂= 75] within the composition range he investigated, viz., 0 < 100x₁ < 43 (the corresponding compositions given in the original paper refer to equivalent fractions of potassium ethanoate).</p> <p>Finally, according to Nadirov and Bakeev (Ref. 4), a eutectic at either 461, or 469, or 476 K (188, 196, 203 °C, respectively) dependently on the method employed for the determination, and 100x₂= 54, and an intermediate compound, ($C_2H_3O_2$)₈CdK₆, incongruently melting at either 518, or 524, or 526 K (245C, 251C, 253 °C, respectively) dependently on the method employed for the determination, are the characteristic features of the system.</p> <p>The general disagreement existing among the above mentioned authors seems not to be attributed to differences in the purity of the alkanoates they employed, although this factor might play some role in the case of Lehrman and Schweitzer (Ref. 1), inasmuch as they report a fusion temperature of component 2, T_{fus}(2)= 565 K (292 °C), which is significantly lower than the generally accepted value of about 579 K (578.7±0.5 K, in Table 1 of the Preface).</p> <p>Indeed, it seems more likely that the formation of complex ions in the melt (Ref. 4) might affect the results obtained with techniques (e.g., the visual polythermal method) implying the observation of the system during cooling. Should these complex ions be sufficiently stable, the actual liquidus might be different as a consequence of largely different cooling rates.</p> <p>Taking into account this possibility, the evaluator is inclined to consider as more reliable the phase diagram suggested by Nadirov and Bakeev (Ref. 4), as it is supported by results obtained with several investigation methods, including X-ray diffractometry which was employed to confirm the existence of the intermediate compound ($C_2H_3O_2$)₈CdK₆.</p> <p>Some doubt, however, might subsist about the interpretation of the slope variation Nadirov and Bakeev (Ref. 4) observed in the plot electric conductivity vs. T, as due to an allotropic transition of potassium ethanoate at 467 K (194 °C). According to Table 1 of the Preface, inter alia, a solid state transition in this salt is to be expected only at T_{trs}(2)= 422.2±0.5 K.</p> <p>REFERENCES:</p> <p>(1) Lehrman, A.; Schweitzer, D. J. Phys. Chem. 1954, 58, 383-384.</p> <p>(2) Il'yasov, I.I. Zh. Obshch. Khim, 1962, 32, 347-349.</p> <p>(3) Pavlov, V.L.; Golubkova, V.V. Vestn. Kiev. Politekh. Inst. Ser. Khim. Mashinostr. <p>AUXILIARY INFORMATION</p>																																																																			
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>A molten salt bath was employed to melt the mixtures placed in a 2.5x20 cm Pyrex tube. The beginning of crystallization (under stirring and by seeding) was observed visually and the corresponding temperature was measured with a potentiometer (16 mV full scale) and a Copper-Constantane thermocouple (whose emf could be read to ±0.02 mV), calibrated at the boiling points of water and benzophenone, and at the fusion points of tin and potassium nitrate.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: "C.P." material added with a few drops of glacial ethanoic acid and dried in an oven at 140 °C. Component 2: "Analytical Reagent" material dried at 140 °C for one week.</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ±0.5 K (compiler).</p>																																																																		

<p>COMPONENTS:</p> <p>(1) Cadmium ethanoate (cadmium acetate); ($C_2H_3O_2$)₂Cd; [543-90-8]</p> <p>(2) Potassium ethanoate (potassium acetate); ($C_2H_3O_2$)₂K₂; [127-08-2]</p>	<p>ORIGINAL MEASUREMENTS:</p> <p>Il'yasov, I.I. ^a T/K values calculated by the compiler.
^b Eutectic temperatures.

Characteristic point(s):

Eutectic, E₁, at 166 °C and 100x₁= 24 (authors).
 Eutectic, E₂, at 148 °C and 100x₁= 42 (authors).
 Eutectic, E₃, at 150 °C and 100x₁= 58 (authors).
 Eutectic, E₄, at 230 °C and 100x₁= 82 (authors).

Intermediate compound(s):

$(C_2H_3O_2)_4CdK_2$, congruently melting at 200 °C (authors).
 $(C_2H_3O_2)_3CdK$, congruently melting at 188 °C (authors).
 $(C_2H_3O_2)_7Cd_3K$, congruently melting at 242 °C (authors).

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Visual polythermal method and time-temperature curves. Mixtures prepared in a glove-box.

ESTIMATED ERROR:

Temperature: accuracy probably ± 2 K (compiler).

SOURCE AND PURITY OF MATERIALS:

Component 1 of analytical purity, dehydrated ($T_{fus}(1)$ = 257-258°C, 530-531 K). Component 2 of analytical purity, heated at 110-140 °C to constant mass ($T_{fus}(2)$ = 306-308°C, 579-581 K).

COMPONENTS: (1) Cadmium ethanoate (cadmium acetate); $(C_2H_3O_2)_2Cd$; [543-90-8] (2) Potassium ethanoate (potassium acetate); $(C_2H_3O_2)K$; [127-08-2]	ORIGINAL MEASUREMENTS: Nadirov, E.G.; Bakeev, M.I. AUXILIARY INFORMATION																																											
METHOD/APPARATUS/PROCEDURE: Visual polythermal method; temperatures measured with a Chromel-Alumel thermocouple and a PP potentiometer. Additional investigations have been performed by means of thermographical analysis, electrical conductometry, and X-ray diffractometry.	SOURCE AND PURITY OF MATERIALS: Not stated. ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																										

<p>COMPONENTS:</p> <p>(1) Cadmium ethanoate (cadmium acetate); ($C_2H_3O_2$)₂Cd; [543-90-8]</p> <p>(2) Sodium ethanoate (sodium acetate); ($C_2H_3O_2$)Na; [127-09-3]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied by Il'yasov (Ref. 1), and Pavlov and Golubkova (Ref. 2). The former author claims the diagram to be of the simple eutectic type, with the invariant at 528 K (255 °C) and $100x_2=68$ (the eutectic composition is given in Ref. 1 as $100x_2=52$ since it refers to the equivalent fraction of component 2), whereas Pavlov and Golubkova suggest the existence of the intermediate compound ($C_2H_3O_2$)₄CdNa₂, congruently melting at 527 K (254 °C), and, accordingly, of two eutectics, E₁, E₂, occurring at 496 K (223 °C) and $100x_2=75$, and at 507 K (234 °C) and $100x_2=58$, respectively.</p> <p>Although the experimental data by Pavlov and Golubkova seem more detailed than those by Il'yasov, the evaluator has no arguments to definitely prefer the diagram shown in Ref. 2, ruling out that of Ref. 1.</p> <p>As a comment, one may notice that the fusion temperature of the intermediate compound given in Ref. 2 is close to that of the eutectic reported in Ref. 1. This might suggest undercooling of Pavlov and Golubkova's samples. In any case, the existence of the intermediate compound suggested by the latter authors should be confirmed with X-ray diffractometry.</p> <p>It is finally to be added that the fusion temperature of component 2 by Il'yasov (601 K) meets that listed in Table 1 of the Preface (601.3±0.5 K), whereas the value by Pavlov and Golubkova (595 K) is significantly lower.</p> <p>REFERENCES:</p> <p>(1) Il'yasov, I.I. Characteristic point(s): Eutectic, E ₁ , at 223 °C and 100x ₁ = 25 (authors). Eutectic, E ₂ , at 234 °C and 100x ₁ = 42 (authors).																																																																			
Intermediate compound(s): $(C_2H_3O_2)_4CdNa_2$, congruently melting at 254 °C (authors).																																																																			
AUXILIARY INFORMATION																																																																			
METHOD/APPARATUS/PROCEDURE: Visual polythermal method and time - temperature curves; temperatures measured with a Copper-Constantane thermocouple. Mixtures prepared in a glove-box and added with 1-3 drops anhydrous ethanoic acid to prevent thermal decomposition of component 1.	SOURCE AND PURITY OF MATERIALS: Component 1 of analytical purity, in part dehydrated, and in part recrystallized from aqueous (2%) ethanoic acid and then dehydrated. Component 2 of analytical purity, recrystallized and then heated at 110-140 °C to constant mass. ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).

<p>AUXILIARY INFORMATION</p>																																											
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal method; temperatures measured with a Chromel-Alumel thermocouple and a PP potentiometer. Additional investigations were performed by means of thermographical analysis and electrical conductometry.</p> <p>NOTE:</p> <p>The occurrence of intermediate compounds in the binaries $C_2H_3O_2$/Cd, K and $C_2H_3O_2$/Cd, Cs was claimed by the same authors in the same paper, and supported with X-ray diffraction patterns: for the present system, on the contrary, no analogous evidence was given. Moreover, the exceedingly large differences among the eutectic temperatures obtained with different techniques is to be stressed.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Not stated.</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																										
	<p>REFERENCES:</p>																																										

<p>COMPONENTS:</p> <p>(1) Cesium ethanoate (cesium acetate) ($C_2H_3O_2$)Cs; [3396-11-0]</p> <p>(2) Potassium ethanoate (potassium acetate) ($C_2H_3O_2$)K; [127-08-2]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>Results on this binary have been repeatedly reported by Diogenov et al. (Refs. 1-3) as a part of their investigations on ternary and reciprocal ternary systems. These authors, who carried out visual polythermal observations on the liquidus, define the system as of the eutectic type with the invariant at either 405 K (132 °C; Ref. 1), or 403 K (130 °C; Ref. 2), or 413 K (140 °C; Ref. 3), and $100x_2 = 28.5$. It is not clear whether the different eutectic temperatures given in Refs. 1-3 come from different sets of measurements or depend on adjustments suggested by the general topology of the particular ternary studied in each paper. A knee in the liquidus branch richer in component 1 (Ref. 1) has been interpreted by these authors as due to a phase transition occurring in this salt at 447 K (174 °C). Diogenov et al. also claimed in a previous paper (Ref. 4) the occurrence in component 2 of a phase transition at 565-566 K (292-293 °C).</p> <p>The DTA investigations by Storonkin et al. (Ref. 5) give further support to the fact that the system is of the eutectic type although the temperature (412 K) and composition ($100x_2 = 32$) of the invariant have been singled out by extrapolation of the two liquidus branches. According to Fig. 3 of the original paper (Ref. 5), the authors assume that the eutectic equilibrium covers the composition range from $100x_2 = 0$ to $100x_2 = 100$. They do not mention, however, the occurrence of any allotropic transition in either component: according to Table 1 this ought to be correct for what concerns component 1, whereas component 2 ought to undergo a phase transition at 422.2 ± 0.5 K.</p> <p>Storonkin et al. (Ref. 5) ascribe the differences between their and Diogenov et al.'s diagram to the higher purity of the salts they employed: indeed, the fusion temperature they report for component 1 [$T_{fus}(1)/K = 467$] is much closer to that listed in Table 1 of the Preface (463±1) than that given by Diogenov et al. (453).</p> <p>As a conclusion, the following remarks should be taken into account.</p> <p>(i) The phase transition temperature reported for cesium ethanoate by Diogenov et al. seems to be unreliable.</p> <p>(ii) The phase transition temperature reported for potassium ethanoate in Ref. 4 (565-566 K) seems also to be unreliable, as it cannot be identified with any transition temperature found by other investigators (Ref. 6).</p> <p>(iii) The eutectic temperature reported by Storonkin et al., viz., 412 K, seems satisfactorily supported by their DTA results, as well as the trend of the liquidus branch richer in cesium ethanoate. On the contrary, there is some doubt about the reliability of the other liquidus branch which, according to these authors, does not show any "knee" to be possibly matched with the expected (see above) phase transition of potassium ethanoate. Consequently, the eutectic composition (attained by extrapolation of the liquidus branches) cannot be considered more reliable than that reported by Diogenov.</p> <p>(iv) Finally, the complete immiscibility in the solid state should be more carefully verified, e.g., by further DTA or DSC investigations extended to extreme compositions.</p> <p>REFERENCES:</p> <p>(1) Nurminskii, N.N. and Diogenov, G.G.; <i>Zh. <p>COMPONENTS:</p> <p>(1) Cesium ethanoate (cesium acetate); ($C_2H_3O_2$)Cs; [3396-11-0]</p> <p>(2) Lithium ethanoate (lithium acetate); ($C_2H_3O_2$)Li; [546-89-4]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was first studied as a side of the ternary $C_2H_3O_2/Cs, Li, Rb$ (Ref. 1), and re-determined by the same group ten years later (Ref. 2). Due to more accurate experimental methods (DTA and X-ray diffractometry) employed in the latter paper (Ref. 2), the phase diagram therein shown seems much more reliable than the previous one (Ref. 1).</p> <p>Accordingly, the system is to be considered as characterized (Ref. 2) by the occurrence of a single intermediate compound, $(C_2H_3O_2)_3CsLi_2$, congruently melting at 563 K (290 °C), and by two eutectics, at 420 K (147 °C) and $100x_1 = 77$, and at 520 K (247 °C) and $100x_1 = 12$, respectively.</p> <p>The main difference of this phase diagram with respect to that presented in the previous work (Ref. 1) is the lack of a further intermediate compound, $(C_2H_3O_2)_2CsLi$ (incongruently melting). Consequently to this lack, however, a large part of the phase diagram of the ternary $C_2H_3O_2/Cs, Li, Rb$ (Ref. 1) ought to be redrawn, which, at the present time has not been done, at least as far as the evaluator knows.</p> <p>The fusion temperatures of component 1 and component 2 as given in Refs. 1, 2 (458-459 K, and 561-563 K, respectively) are not far from those listed in Table 1 of the Preface (463±1 K, and 557±2 K, respectively). Moreover, no mention is made of the occurrence of phase transitions in either component, which is again in agreement with Table 1 of the Preface, although in disagreement with the fact that in other papers by the same group (see, e.g., Ref. 3) component 1 is described as undergoing a phase transition at 477 K (174 °C).</p> <p>REFERENCES:</p> <p>(1) Diogenov, G.G.; Sarapulova, I.F. <p>AUXILIARY INFORMATION</p>																																																																																											
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>A thermographical analysis was performed with a Kurnakov pyrometer mod. 1959 (reference material: Al_2O_3). Only heating traces (at the heating rate of 5-6 °C/min) were recorded due to the tendency of the melts to undercool. Supplementary visual polythermal observations are also tabulated. X-ray diffraction patterns were used to obtain information on the intermediate compound.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Not stated. Component 1 undergoes a phase transition at $t_{trs}(1)/^\circ C = 35$.</p>																																																																																										
	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																																																																										
	<p>REFERENCES:</p>																																																																																										

<p>COMPONENTS:</p> <p>(1) Cesium ethanoate (cesium acetate); ($C_2H_3O_2$)Cs; [3396-11-0]</p> <p>(2) Sodium ethanoate (sodium acetate); ($C_2H_3O_2$)Na; [127-09-3]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was first investigated as a side of the ternary $C_2H_3O_2/Cs, Na, Rb$ by Diogenov and Sarapulova (Ref. 1), who reported a eutectic at 388 K (115 °C) and $100x_1 = 68$, on the basis of visual polythermal observations.</p> <p>The liquidus by these authors shows a knee at about 585 K and $100x_1$ about 5, which might be identified with the phase transition of ($C_2H_3O_2$)Na reported by Diogenov at 596 K (323 °C; Ref. 2), and by Gimel'shtein and Diogenov at 583-584 K (310-311 °C; Ref. 3). However, such figures do not meet any of the high temperature T_{trs} values by other authors (Ref. 4), which range between 511-513 and 527±15 K.</p> <p>Substantially analogous results, including the knee (for which no explanation is offered), have been reported also by Storonkin et al. (Ref. 5) for the liquidus branch richer in component 2. The other branch by these authors, however, lies significantly above the corresponding curve by Diogenov and Sarapulova: the difference has been attributed by Storonkin et al. to the higher purity of the cesium ethanoate they employed.</p> <p>According to the latter authors (Ref. 5), who carried out DTA determinations through most of the composition range, the eutectic temperature is 392 K, and the eutectic composition (which was obtained by extrapolation, due to the tendency to undercool of the melts of composition close to x_E) is $100x_1 = 64$.</p> <p>In the opinion of the evaluator, the following points should be remarked.</p> <p>(i) Neither Ref. 1 nor Ref. 5 report the phase transition of sodium ethanoate observed by other authors (Ref. 4) at 510-530 K, i.e., well above the eutectic temperature of the binary.</p> <p>(ii) No comment is explicitly made in either work on the apparent knee of the liquidus branch richer in component 2.</p> <p>(iii) No experimental support is given to rule out the occurrence of solid solutions in the regions of the phase diagram close to the pure components.</p> <p>(iv) The phase transition of cesium ethanoate observed by Nurminskii and Diogenov (Ref. 6) at 447 K is neither confirmed nor mentioned in the present investigation (Ref. 1) by the same group.</p> <p>Accordingly, it seems justified to cast some doubts about the reliability of the upper part of the liquidus branch richer in component 2, whereas the eutectic temperature (390±2 K) and composition ($100x_2 = 66±2$) seem satisfactorily supported by the data available.</p> <p>REFERENCES:</p> <p>(1) Diogenov, G.G.; Sarapulova, I.F. 	<p>REFERENCES:</p>

<p>COMPONENTS:</p> <p>(1) Cesium ethanoate (cesium acetate); ($C_2H_3O_2$)Cs; [3396-11-0]</p> <p>(2) Rubidium ethanoate (rubidium acetate); ($C_2H_3O_2$)Rb; [563-67-7]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied as a side of the ternary $C_2H_3O_2$/Cs, Na, Rb (Ref. 1), and of the reciprocal ternary Cs, Rb/$C_2H_3O_2$, NO_2 (Ref. 2), respectively.</p> <p>Both papers give substantially analogous results, i.e., a liquidus with a minimum at 446 K (173 °C) and $100x_1 = 72$ (Ref. 1), and at 445 K (172 °C) and $100x_1 = 71$ (Ref. 2), respectively. It is, however, not clear whether the slight differences in the coordinates of the minimum as given in Ref. 1 and Ref. 2, respectively, come from different sets of determinations, or from a suitable adjustment improving the overall presentation of the ternary involved. It is also to be remarked that, although coming from the same group, a significant difference exists between the $T_{fus}(2)$ values given in Ref. 1 (453.2 K) and Ref. 2 (460 K), the corresponding value given in Table 1 being 463 ± 1 K.</p> <p>Moreover, in neither paper the phase transition of rubidium ethanoate, occurring at either 489-493 K (Ref. 3), or 498 ± 1 (Preface, Table 1) is explicitly mentioned, although, e.g., it might reasonably justify the knee observed at about 498 K (Ref. 1) in the liquidus branch richer in component 2.</p> <p>The inspection of the liquidus of both ternaries mentioned above strongly supports the occurrence of solid solutions in the $C_2H_3O_2$/Cs, Rb side binary. However, the limits of the T, x_2 field covered in the binary by these solutions seem poorly defined, in particular for what concerns the compositions close to pure component 2, and for temperatures close to the transition temperature of this salt. Thence, in the evaluator's opinion, an investigation of the solidus would be desirable, in order to attain more satisfactory information about these points.</p> <p>REFERENCES:</p> <p>(1) Diogenov, G.G.; Sarapulova, I.F. <p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The visual polythermal method as well as time-temperature curves were employed. The temperatures were measured with a Chromel-Alumel thermocouple checked at the freezing temperatures of Zn, K₂Cr₂O₇, Cd, Sn, and benzoic acid.</p> <p>NOTE:</p> <p>The formation of glasses in this system seems likely. Accordingly, one should expect marked undercooling over a large composition range which would make the results of visual polythermal observations less reliable than usual. The lack of any further experimental evidence (e.g., from X-ray diffractometry) justifies casting doubts about the actual existence of the intermediate compound(s).</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: obtained by reacting Cs₂CO₃ and ethanoic acid, and kept in a dessicator in the presence of P₂O₅ until constant mass. Component 2: ($C_2H_3O_2$)₂Zn·2H₂O of analytical purity dried to constant mass at 110 °C.</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ±2 K (compiler).</p> <p>REFERENCES:</p>

<p>COMPONENTS:</p> <p>(1) Potassium ethanoate (potassium acetate); ($C_2H_3O_2$)K; [127-08-2]</p> <p>(2) Lithium ethanoate (lithium acetate); ($C_2H_3O_2$)Li; [546-89-4]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p>	
<p>The system potassium ethanoate - lithium ethanoate was investigated by Diogenov (visual polythermal analysis, 1956; Ref. 1), Pochtakova (visual polythermal analysis, 1965; Ref. 2), Sokolov and Tsindrik (visual polythermal analysis, supplemented with DTA, 1969; Ref. 3), and Gimel'shtein (DTA, supplemented with X-ray patterns, 1970, 1971; Refs. 4, 5, respectively).</p>	
<p>Phase transitions are reported at 571 K (298 °C) by Diogenov (Ref. 1), at 331 and 428 K (58 and 155 °C, respectively) by Sokolov (Ref. 6, quoted in Refs. 2, 3), and at 428 K (155 °C) by Gimel'shtein (Ref. 5) for component 1; at 540 K (267 °C) by Diogenov (Ref. 1), and at 405 K (132 °C) by Gimel'shtein (Ref. 5) for component 2. In Table 1 of the Preface mention is made of a transition at 422.2 ± 0.5 K for component 1, whereas no transition is reported for component 2.</p>	
<p>Diogenov (Ref. 1) investigated the binary concerned here as a side system of the ternary $C_2H_3O_2/K, Li, Na$, and claimed the existence of two congruently melting intermediate compounds, i.e., $(C_2H_3O_2)_2KLi$ and $(C_2H_3O_2)_3KLi_2$, respectively. The existence of the former, inferred by Diogenov from discontinuities observed in the liquidus of the binary itself and of two internal cuts of the ternary, was denied by all subsequent authors. In particular, no evidence of the existence of a crystallization field attributable to a 1:1 compound was found either by Pochtakova (Ref. 2) in her re-investigation of the ternary $C_2H_3O_2/K, Li, Na$, or by Sokolov and Tsindrik (Ref. 3), and Gimel'shtein (Ref. 4) in their studies of the topology of the reciprocal ternary $K, Li/C_2H_3O_2, NO_3$. The thermographical traces recorded by Gimel'shtein (and detailed in Ref. 5) support satisfactorily the assertion that in the mixtures of potassium and lithium ethanoates only the intermediate compound $(C_2H_3O_2)_3KLi_2$ does form, which melts congruently at 547 ± 2 K (Refs. 2; 4, 5), and gives eutectics with each of the component salts.</p>	
<p>In the figure, the visual data by Pochtakova (Ref. 2) are plotted, along with the thermographical ones obtained by Gimel'shtein (Ref. 5) to give a comprehensive and reasonably reliable representation of the liquidus, solidus, and subsolidus. The main discrepancies between the two authors occur in the fusion temperatures of the pure components:</p>	
<p>$T_{fus}(1)/K = 575, 585$ (Refs. 2, 5, respectively); $T_{fus}(2)/K = 557, 565$ (Refs. 2, 5, respectively).</p>	
<p>The more correct probably are those reported in Ref. 2, which are closer to $T_{fus}(1)/K = 578.7 \pm 0.5$, and $T_{fus}(2)/K = 557 \pm 2$, reported in Table 1 of the Preface. These discrepancies, however, do not affect substantially the overall features of the phase diagram.</p>

AUXILIARY INFORMATION																																																																																																																			
METHOD/APPARATUS/PROCEDURE: Visual polythermal method; temperatures measured with a Chromel-Alumel thermocouple.	SOURCE AND PURITY OF MATERIALS: "Chemically pure" materials, recrystallized twice and dehydrated by prolonged heating. Components 1 and 2 undergo phase transitions at $t_{trs}(1)/^\circ C = 298$ and $t_{trs}(2)/^\circ C = 267$, respectively, according to Fig. 1 of the original paper (compiler).																																																																																																																		
	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																																																																																																		
	REFERENCES:

AUXILIARY INFORMATION																																																																																																																			
METHOD/APPARATUS/PROCEDURE: Visual polythermal method, supplemented with differential thermal analysis. NOTE: The system was investigated only at $0 \leq 100x_2 \leq 55$ due to thermal instability of component 2. The fusion temperature of component 1 (575 K) is not far below that reported in Table 1 of the Preface (578.7+0.5 K), where, however, only one solid state transition (at 422.2+0.5 K) is mentioned, instead of the two ones (at 428 and 331 K, respectively) quoted by Pochtakova from Ref. 1.	SOURCE AND PURITY OF MATERIALS: Component 1: "chemically pure" material recrystallized and dried at 200 °C to constant mass (phase transitions at $t_{trg}(1)/^\circ C = 58, 155$; Ref. 1). Component 2: prepared (Ref. 2) by reacting the ("chemically pure") carbonate with a slight excess of ethanoic acid of analytical purity (phase transitions at $t_{trg}(2)/^\circ C = 152, 176$).																																																																																																																		
	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).

CRITICAL EVALUATION:	
This system has been the most widely studied during the last 70 years. The opinions by the different authors are summarized hereafter.	
(1) <u>Baskov (1915; Ref. 1).</u> $T_{fus}(1) = 568.2 \text{ K (} 295.0 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 593.2 \text{ K (} 320.0 \text{ }^\circ\text{C)}$; continuous series of solid solutions with a minimum, m, at $496.2 \text{ K (} 223.0 \text{ }^\circ\text{C)}$ and $100x_2 = 46$ (method: thermal analysis; liquidus and solidus investigated).	
(2) <u>Bergman; Evdokimova (1956; Ref. 2).</u> $T_{fus}(1) = 575 \text{ K (} 302 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 599 \text{ K (} 326 \text{ }^\circ\text{C)}$; $T_{trs}(2) = 527 \text{ K (} 254 \text{ }^\circ\text{C)}$; eutectic, E, at $497 \text{ K (} 224 \text{ }^\circ\text{C)}$ and $100x_2 = 45$ (method: visual polythermal analysis, supplemented with three DTA records; liquidus and solidus investigated).	
(3) <u>Diogenov; Erlykov (1958; Ref. 3).</u> $T_{fus}(1) = 583.5 \text{ K (} 310.5 \text{ }^\circ\text{C)}$; $T_{trs}(1) = 569 \text{ K (} 296 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 610 \text{ K (} 337 \text{ }^\circ\text{C)}$; $T_{trs}(2) = 599 \text{ K (} 326 \text{ }^\circ\text{C)}$; continuous series of solid solutions with a minimum, m, at $501 \text{ K (} 228 \text{ }^\circ\text{C)}$ and $100x_2 = 45$ (method: visual polythermal analysis; liquidus only investigated).	
(4) <u>Golubeva; Bergman; Grigor'eva (1958; Ref. 4).</u> Intermediate compound $(C_2H_3O_2)_3K_2Na$, incongruently melting at $513 \text{ K (} 240 \text{ }^\circ\text{C)}$ (method: visual polythermal analysis).	
(5) <u>Sokolov; Pochtakova (1958; Ref. 5).</u> $T_{fus}(1) = 574 \text{ K (} 301 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 604 \text{ K (} 331 \text{ }^\circ\text{C)}$; [$T_{trs}(2) = 527 \text{ K (} 254 \text{ }^\circ\text{C)}$; quoted by the authors from Ref. 2]; eutectic, E_1 , at $513 \text{ K (} 240 \text{ }^\circ\text{C)}$ and $100x_2 = 38.5$; eutectic, E_2 , at $508 \text{ K (} 235 \text{ }^\circ\text{C)}$ and $100x_2 = 46.5$; intermediate compound, $(C_2H_3O_2)_5K_3Na_2$, congruently melting at $514 \text{ K (} 241 \text{ }^\circ\text{C)}$ (method: visual polythermal analysis; liquidus only investigated).	
(6) <u>Nesterova; Bergman (1960; Ref. 6).</u> $T_{fus}(1) = 579 \text{ K (} 306 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 601 \text{ K (} 328 \text{ }^\circ\text{C)}$; peritectic, P, at $511 \text{ K (} 238 \text{ }^\circ\text{C)}$ and $100x_2 = 36.5$; eutectic, E , at $505 \text{ K (} 232 \text{ }^\circ\text{C)}$ and $100x_2 = 50$; intermediate compound, $(C_2H_3O_2)_3K_2Na$, incongruently melting (method: visual polythermal analysis; liquidus only investigated).	
(7) <u>Il'yasov; Bergman (1960; Ref. 7).</u> $T_{fus}(1) = 579 \text{ K (} 306 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 601 \text{ K (} 328 \text{ }^\circ\text{C)}$; peritectic, P, at $523\text{--}529 \text{ K (} 250\text{--}256 \text{ }^\circ\text{C)}$ and $100x_2 = 35$; eutectic, E , at $513 \text{ K (} 240 \text{ }^\circ\text{C)}$ and $100x_2 = 50$; intermediate compound, $(C_2H_3O_2)_3K_2Na$, incongruently melting (method: visual polythermal analysis; liquidus only investigated).	
(8) <u>Diogenov; Sarapulova (1964; Ref. 8).</u> $T_{fus}(1) = 583 \text{ K (} 310 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 608 \text{ K (} 335 \text{ }^\circ\text{C)}$; eutectic, E_1 , at $513 \text{ K (} 240 \text{ }^\circ\text{C)}$ (composition not reported); eutectic, E_2 , at $508 \text{ K (} 235 \text{ }^\circ\text{C)}$ (composition not reported); intermediate compound, $(C_2H_3O_2)_5K_3Na_2$, congruently melting (method: visual polythermal analysis).	
(9) <u>Sokolov; Pochtakova (1967; Ref. 9).</u> $T_{fus}(1) = 575 \text{ K (} 302 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 604 \text{ K (} 331 \text{ }^\circ\text{C)}$; solid state transitions at 428 and $331 \text{ K (} 155$ and $58 \text{ }^\circ\text{C)}$ for component 1, at $511, 403, 391,$ and $331 \text{ K (} 238, 130, 118,$ and $58 \text{ }^\circ\text{C)}$ for component 2; eutectic, E_1 , at $513 \text{ K (} 240 \text{ }^\circ\text{C)}$ and $100x_2 = 38.5$; eutectic, E_2 , at $506 \text{ K (} 233 \text{ }^\circ\text{C)}$ and $100x_2 = 46.5$; intermediate compound, $(C_2H_3O_2)_5K_3Na_2$, congruently melting at $513\text{--}514 \text{ K (} 240\text{--}241 \text{ }^\circ\text{C)}$ (method: thermographical analysis, supplemented with visual polythermal measurements and microscopic observations in polarized light).	
(10) <u>Diogenov; Chumakova (1975; Ref. 10).</u> $T_{fus}(1) = 575 \text{ K (} 302 \text{ }^\circ\text{C)}$; $T_{fus}(2) = 599 \text{ K (} 326 \text{ }^\circ\text{C)}$; peritectic, P, at $513 \text{ K (} 240 \text{ }^\circ\text{C)}$ (composition not reported); eutectic, E, at $510 \text{ K (} 237 \text{ }^\circ\text{C)}$ (composition not reported); intermediate compound, $(C_2H_3O_2)_5K_3Na_2$, incongruently melting (method: visual polythermal analysis).	

COMPONENTS:	EVALUATOR:
(1) Potassium ethanoate (potassium acetate); (C ₂ H ₃ O ₂)K; [127-08-2]	Franzolini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).
(2) Sodium ethanoate (sodium acetate); (C ₂ H ₃ O ₂)Na; [127-09-3]	

CRITICAL EVALUATION (cont.d.):

(11) Storonkin; Vasil'kova; Tarasov (1977; Ref. 11).

$T_{fus}(1) = 584$ K (311 °C); $T_{fus}(2) = 607$ K (334 °C); eutectic, E, at 511 K (238 °C) and $100x_2 = 46$ (method: differential thermal analysis and "contact polythermal method" under polarized light, supplemented with IR spectroscopy).

Information from different sources on the thermophysics of both components is conflicting, possibly due - inter alia - to hygroscopicity, and to the fact that solid state transitions are characterized by a remarkable sluggishness.

$T_{fus}(1)$ values ranging between 565 and 584 K, and $T_{fus}(2)$ values ranging between 592 and 610 K can be found in the literature (Ref. 12). The DSC data from Preface Table 1, i.e., $T_{fus}(1) = 578.7 \pm 0.5$ K and $T_{fus}(2) = 601.3 \pm 0.5$ K, are thought to be reasonably trustworthy, being supported by independent cryometric measurements by the same group (Ref. 12). Concerning in particular the T_{fus} data given in Refs. 1-11, the following remarks can be made. Poor reliability seems to be attached to the fusion temperatures from Refs. 1, 3, 8, 10, 11. Indeed: (i) Baskov (Ref. 1), who studied the system in 1915, might have not had at disposal high purity samples, thus obtaining too low T_{fus} values [$T_{fus}(1) = 568.2$ K; $T_{fus}(2) = 593.2$ K]; (ii) Diogenov et al.'s figures [$T_{fus}(1) = 583.5$ K (1958; Ref. 3), 583 K (1964; Ref. 8), and 575 K (1975; Ref. 10); $T_{fus}(2) = 610$ K (1958; Ref. 3), 608 K (1964; Ref. 8), and 599 K (1975; Ref. 10)] look as doubtful, due to excessive fluctuation; (iii) Storonkin et al.'s figures [$T_{fus}(1) = 584$ K; $T_{fus}(2) = 607$ K (1977; Ref. 11)] seem also to be doubtful and for the same reason, inasmuch as in previous papers Storonkin, Vasil'kova, and Potemin (1974; Ref. 13) gave $T_{fus}(2) = 601$ K, while Potemin, Tarasov, and Panin (1973; Ref. 14) gave $T_{fus}(1) = 581$ K, $T_{fus}(2) = 604$ K. Instead, the agreement with T_{fus} data from Preface Table 1 is satisfactory for the most recent figures by Bergman et al. (Refs. 6, 7), and still acceptable for those by Sokolov and Pochtakova (Refs. 5, 9).

As for the solid state transitions, the situation is rather puzzling, as shown in the following table.

Salt	T_{trs}/K	Method	Year	Ref.
C ₂ H ₃ O ₂ K	428, 331	Vis. pol.	1956	15

	337	DTA	1976	23

Vis. pol.: visual polythermal analysis; Dilat.: dilatometry;
(...): provisional data.

Potassium ethanoate was submitted to X-ray investigation by Hatibarua and Parry (Ref. 19), who obtained evidence for a monoclinic → monoclinic transformation at about 348 K, and for a monoclinic → orthorhombic transformation at 428 K. Allowance being made for some fluctuations in the T_{trs} values, it can be asserted that the occurrence of the former transition is supported by Sokolov's (Ref. 15), and Hazlewood et al.'s (Ref. 18) findings, while on the occurrence of the latter transition all the authors concerned agree, but for Diogenov et al. (Refs. 3, 16). These, in turn, are alone in claiming that component 1 undergoes a transformation at a temperature as high as 560-570 K: the evaluator, however, is inclined to think that the existence of the latter

<p>COMPONENTS:</p> <p>(1) Potassium ethanoate (potassium acetate); ($C_2H_3O_2$)K; [127-08-2]</p> <p>(2) Sodium ethanoate (sodium acetate); ($C_2H_3O_2$)Na; [127-09-3]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION (cont.d):</p> <p>transformation is quite doubtful.</p> <p>The number and location of solid state transitions in sodium ethanoate is still an open question, and the pertinent data are the most uncertain among those listed in Preface Table 1. It can only be said that the occurrence of a transition at 510-530 K seems to be reasonably supported (Refs. 2, 15, and Preface Table 1), whereas insufficient experimental evidence has been provided so far for the remaining transitions, including that reported by Diogenov et al. (Refs. 21, 3, 22) at 580-600 K.</p> <p>Concerning the topology of the phase diagram, the evaluator is inclined not to take into account the findings by: (i) Baskov (Ref. 1), because reasonable doubts exist - as said above - about the purity of the salts he could have at disposal in 1915; (ii) Diogenov et al. (Refs. 3, 8, 10), for both the above made remarks on the phase transformation temperatures they report, and their conflicting assertions on the phase relations (continuous series of solid solutions in Ref. 3; congruently melting intermediate compound in Ref. 8; incongruently melting intermediate compound in Ref. 10).</p> <p>Storonkin et al. (Ref. 11) quoted in their paper Refs. 1-5, 7, 8, and - inter alia - asserted correctly that it is hard to state the composition of an incongruently melting intermediate compound on the only basis of visual observations carried out on the liquidus. They asserted also that: (i) due to undercooling of the molten mixtures of composition $50 \leq 100x_1 \leq 60$, no reliable information could be drawn from their liquidus on the formation of any intermediate compound; and (ii) their supplementary IR measurements gave no evidence of the existence of such compounds. Accordingly, they claimed the occurrence of a eutectic as the only invariant, and singled out its composition ($100x_2 = 46$) by extrapolation of the part of the liquidus branches they were able to investigate. Storonkin et al. (Ref. 11), however, employed salts on the purity of which doubts - as said above - are not unreasonable, and were not aware of the more recent paper by Sokolov and Pochtakova (Ref. 9).</p> <p>Bergman et al. in their oldest paper (Ref. 2) claimed the existence of a eutectic, but subsequently changed their mind (Refs. 4, 6, 7), and asserted that the incongruently melting compound $(C_2H_3O_2)_3K_2Na$ was formed. It can be observed that the fusion temperatures of the pure components given in their most recent paper (Ref. 7), i.e., $T_{fus}(1)/K = 579$ and $T_{fus}(2)/K = 601$, are in excellent agreement with the corresponding values listed in Table 1 of the Preface (578.7 ± 0.5 K, and 601.3 ± 0.5 K, respectively), and that they make no mention of difficulties in measuring the liquidus. The composition they stated for the intermediate compound, however, was not supported by any investigation of the solidus, and poor reliability is to be attached to the peritectic temperature they suggested (511 K in Ref. 6; 523-529 K in Ref. 7).</p> <p>Finally, Sokolov and Pochtakova (Refs. 5, 9) in their more recent paper (Ref. 9) employed thermographical analysis to support the assertion already made in Ref. 5 that the intermediate compound $(C_2H_3O_2)_5K_3Na_2$ is formed in the binary. They too seem not to have met special difficulties in measuring the liquidus.</p> <p>In conclusion, the evaluator is inclined to think that:</p> <ul style="list-style-type: none"> - in the composition range $40 \leq 100x_2 \leq 100$ a eutectic exists at 508 ± 3 K and $100x_2 = 48 \pm 2$; - an intermediate compound is likely formed: it ought to have composition $(C_2H_3O_2)_5K_3Na_2$, and melt congruently (thus giving origin to a second eutectic in the composition range $0 \leq 100x_2 \leq 40$); - limited mutual solubility exists on both sides of the diagram; <p>The second conclusion is based on Sokolov and Pochtakova's (Refs. 5, 9) information, which seems the most reliable at disposal so far, although being not fully free from criticisms (see, e.g., the above made remarks on the solid state transformations occurring in pure components).</p> <p>The last assertion is supported by the findings of Sokolov and Pochtakova (Ref. 9), and Storonkin et al. (Ref. 11). Moreover, Braghetti et al. (Ref. 24) found for sodium</p>	

<p>COMPONENTS:</p> <p>(1) Potassium ethanoate (potassium acetate); (C₂H₃O₂)K; [127-08-2]</p> <p>(2) Sodium ethanoate (sodium acetate); (C₂H₃O₂)Na; [127-09-3]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION (cont.d):</p> <p>ethanoate dissolved in potassium ethanoate a limiting value</p> <p>$\text{Lim } (\Delta T/m) = 14.6 \text{ K molality}^{-1}$ $m \rightarrow 0$</p> <p>(ΔT: experimental freezing point depression; m: molality of the solute), whereas the cryometric constant of potassium ethanoate is $18.0 \pm 0.3 \text{ K molality}^{-1}$ (Ref. 24).</p> <p>REFERENCES:</p> <p>(1) Baskov, A.; Zh. ^a T/K values calculated by the compiler.

^b Temperatures of starting crystallization (authors).

^c Temperatures of ending crystallization (authors).

^d Eutectic temperatures (authors).

^e Solid-solid transition of the intermediate compound (authors).

^f Interaction of the intermediate compound with the solid solution rich in component 1 (authors).

^g Reaction $2[(C_2H_3O_2)_3K_2Na] = (C_2H_3O_2)_5K_3Na_2 + (C_2H_3O_2)K$ (authors).

^h Limits of the solid solution regions (authors).

Characteristic point(s): Eutectic, E_1 , at 240 °C and $100x_1 = 61.5$ (compiler).

Eutectic, E_2 , at 233 °C and $100x_1 = 53.5$ (compiler).

Intermediate compound: $(C_2H_3O_2)_5K_3Na_2$ congruently melting at 240 °C (compiler), or 241 °C according to the figure of the original paper.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Thermographical analysis (with recording of the heating traces), supplemented with (not detailed) visual polythermal measurements, and microscopic observations on solid (previously melted) samples in polarized light.

SOURCE AND PURITY OF MATERIALS:

"Chemically pure" materials employed. Component 1 melts at 302 °C and undergoes phase transitions at $t_{trs}(1)/^\circ C = 58, 155$ (Ref. 1). Component 2 melts at 331 °C and undergoes phase transitions at $t_{trs}(2)/^\circ C = 58, 118, 130, 238$ (Ref. 1).

ESTIMATED ERROR:

Temperature: accuracy probably ± 2 K (compiler).

<p>^a T/K values calculated by the compiler; ^b Eutectic temperatures (filled circles); ^c Metastable.</p> <p>Characteristic point(s): Eutectic, E₁, at 174.9 °C; composition not stated (about 100x₂ = 30, compiler). Eutectic, E₂, at 169.5 °C; composition not stated (about 100x₂ = 43, compiler). Eutectic, E₃, at 159.9 °C; and 100x₂ = 62.5 (authors). Eutectic, E₄, at 132.2 °C; composition not stated (about 100x₂ = 79, compiler).</p> <p>Intermediate compounds: $(C_2H_3O_2)_4K_2Pb$, congruently melting at 183 °C (compiler). $(C_2H_3O_2)_3KPb$, congruently melting at 194 °C (compiler). $(C_2H_3O_2)_5KPb_2$, congruently melting at 169 °C (compiler).</p>																																																																																												
AUXILIARY INFORMATION																																																																																												
METHOD/APPARATUS/PROCEDURE: <p>The mixtures (20-35 g) were weighed into 2.5x20 cm Pyrex tubes, then suspended in a bath of the molten eutectic of Ca, K, Li nitrates. When necessary to prevent decomposition, two drops of glacial ethanoic acid were added. Due to the tendency to supercool, it was preferred to take the temperatures of complete melting. Cooling curves were used to obtain a few eutectic temperatures. Temperatures were measured mainly with a Copper-Constantane thermocouple (checked at the boiling point of water, and at the melting points of Sn, KNO₃, and of the Sn-Pb eutectic mixture). In a few cases a mercury thermometer was employed.</p>	SOURCE AND PURITY OF MATERIALS: <p>Component 1: material of "chemically pure" grade, recrystallized from distilled water, then dried in an oven at 100 °C for one week, and at 140 °C for six hours before weighing. Component 2: material of "chemically pure" grade, recrystallized from distilled water acidified with ethanoic acid, then dried at 100 °C.</p>																																																																																											
NOTE: <p>It can be remarked that the fusion temperature of component 1 found by Lehrman and Leifer does not agree with recent literature data which range mostly between 574 and 584 K (Ref. 1).</p>	ESTIMATED ERROR: <p>Temperature: accuracy ± 0.5 K (authors).</p> REFERENCES: (1) Sanesi, M.; Cingolani, A.; Tonelli, P.L.; Franzosini, P. <i>Thermal Properties, in Thermodynamic and Transport Properties of Organic Salts</i> , IUPAC Chemical Data Series No. 28 (Franzosini, P.; Sanesi, M.; Editors), Pergamon Press, Oxford, 1980 , 29-115.																																																																																											

<p>COMPONENTS:</p> <p>(1) Potassium ethanoate (potassium acetate); ($C_2H_3O_2$)K; [127-08-2] (2) Rubidium ethanoate (rubidium acetate); ($C_2H_3O_2$)Rb; [563-67-7]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was first studied with the visual polythermal method by Diogenov and Sarapulova (Ref. 1). Subsequently, Sarapulova et al. (Ref. 2) carried out a thermographical analysis of the system, supplemented with a few visual observations, and X-ray diffractograms recorded on the pure components and five (previously melted) intermediate mixtures.</p> <p>Only minor differences occur between the liquidus curves by either source. The fusion temperatures of the pure components, i.e., $T_{fus}(1) = 583$ K (Refs. 1, 2), and $T_{fus}(2) = 509$ K (visual; Refs. 1, 2) or 511 K (thermographical; Ref. 2) are acceptable, although somewhat lower than the corresponding values listed in Table 1 of the Preface, i.e., $T_{fus}(1) = 578.7 \pm 0.5$ K, and $T_{fus}(2) = 514 \pm 1$ K. Poorer agreement, on the contrary, exists between the solid state transition temperatures reported in Ref. 2 (i.e., 327 K and 428 K for component 1, and 488 K for component 2), and those listed in Table 1 of the Preface (i.e., 422.2 ± 0.5 K for component 1, and 498 ± 1 K for component 2).</p> <p>On the basis of the X-ray patterns mentioned above, Sarapulova et al. (Ref. 2) assert that complete miscibility exists even at room temperature, although giving no information about the phase of component 1 they assume to be involved in these solid solutions.</p> <p>In the evaluator's opinion, doubts are to be cast about the solid state transition at 327 K in component 1. Should it actually exist, the lower part of the diagram shown in Ref. 2 would require completion, whereas, in its absence, the picture of the phase relations would be substantially correct.</p> <p>REFERENCES:</p> <p>(1) Diogenov, G.G.; Sarapulova, I.F. AUXILIARY INFORMATION																																																																																					
METHOD/APPARATUS/PROCEDURE: A thermographical analysis was performed with a Kurnakov pyrometer Mod. 1959 (reference material: Al_2O_3). Only heating traces (at the heating rate of 5-6 °C/min) were recorded due to the tendency of the melts to undercool. Supplementary visual polythermal observations are also tabulated. X-ray diffraction patterns were used to obtain information on the solid solutions.	SOURCE AND PURITY OF MATERIALS: Not stated. Component 1 undergoes phase transitions at $t_{trs}(1)/^\circ C = 54, 155$. Component 2 undergoes a phase transition at $t_{trs}(2)/^\circ C = 215$.																																																																																				
ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).	REFERENCES:

AUXILIARY INFORMATION																																																																			
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis supplemented with conductometry and occasionally with X-ray investigations. Temperatures of initial crystallization measured with a thermocouple.	SOURCE AND PURITY OF MATERIALS: Component 1: material recrystallized three times and dried at 110-120 °C. Component 2: $(C_2H_3O_2)_2Zn \cdot 2H_2O$ of analytical purity, recrystallized twice and dried at 140 °C.																																																																		
NOTE: It can be observed that the fusion temperature of component 1 reported by Nadirov and Bakeev (579 K) is in fair agreement with the corresponding value listed in Table 1 of the Preface (578.7±0.5 K), whereas the fusion temperature of component 2 (509 K) is noticeably lower than other recent data by different investigators (Ref. 1).	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler). REFERENCES: (1) Sanesi, M.; Cingolani, A.; Tonelli, P.L.; Franzosini, P. <i>Thermal Properties, in Thermodynamic and Transport Properties of Organic Salts</i> , IUPAC Chemical Data Series No. 28 (Franzosini, P.; Sanesi, M.; Editors), Pergamon Press, Oxford 1980, 29-115.																																																																		

<p>COMPONENTS:</p> <p>(1) Lithium ethanoate (lithium acetate); (C₂H₃O₂)Li; [546-89-4]</p> <p>(2) Sodium ethanoate (sodium acetate); (C₂H₃O₂)Na; [127-09-3]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was investigated by Diogenov (Ref. 1), by Pochtakova (Ref. 2), and again by Diogenov and Chumakova (Ref. 3) with substantially discrepant conclusions.</p> <p>Diogenov, in his earlier paper (Ref. 1), claimed the existence of: (i) eutectic, E₁, occurring at 499-500 K (226-227 °C), and (likely) 100x₁ = 81.5 (the latter figure being quoted in Ref. 4, which is a later paper by the same author); (ii) eutectic, E₂, occurring at 433 K (160 °C) and 100x₁ = 57; and (iii) the intermediate compound (C₂H₃O₂)₅Li₄Na, congruently melting at 500 K (227 °C).</p> <p>These results, however, were not confirmed in Ref. 3, where Diogenov and Chumakova reported approximately the same coordinates for E₁, viz., 492-494 K (219-221 °C) and 100x₁ about 78, but completely different fusion temperature for E₂, viz., either 486 K (213 °C; Fig. 2 of the original paper), or 449 K (176 °C; Fig. 4 of the original paper). Moreover they suggested for the intermediate compound a new formula, i.e., (C₂H₃O₂)₄Li₃Na.</p> <p>Finally, it is to be noted that the fusion temperatures given in Refs. 1, 3 for component 2 differ by 11 K, and the phase transitions reported in Ref. 1, i.e., T_{trs}(1) = 530 K (257 °C), and T_{trs}(2) = 596 K (323 °C), do not meet any value of Table 1 of the Preface.</p> <p>In conclusion, the poor reproducibility of the results by Diogenov's group does not allow one to take them into consideration for assessing the actual diagram of this system.</p> <p>Conversely, Pochtakova's data (Ref. 2) seem more reliable, although among the phase transition temperatures of component 2 quoted by the author from Ref. 5, i.e., 331, 391, 403, and 511 K (58, 118, 130, and 238 °C, respectively), only two can be identified with those listed in Preface, Table 1. This disagreement, however, does not seem, in the evaluator's opinion, to involve heavily the reliability of the liquidus, due also to the fact that the fusion temperatures of both pure components (604 K for component 2, and 557 K for component 1, respectively) are close to those reported in Preface, Table 1 (601.3±0.5 and 557±2 K, respectively).</p> <p>Accordingly, the phase diagram by Pochtakov can be accepted with some confidence: in particular, the composition of the congruently melting intermediate compound, i.e., (C₂H₃O₂)₅Li₃Na₂, seems satisfactorily defined by the dome exhibited by the liquidus.</p>

<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal method.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Not stated. Component 1: $t_{fus}(1)/^{\circ}C = 291$ (Fig. 3 of the original paper). Component 2: $t_{fus}(2)/^{\circ}C = 326$ (Fig. 1 of the original paper).</p> <hr/> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably <u>+2</u> K (compiler).</p> <hr/> <p>REFERENCES:</p>

<p>COMPONENTS:</p> <p>(1) Lithium ethanoate (lithium acetate); (C₂H₃O₂)Li; [546-89-4]</p> <p>(2) Rubidium ethanoate (rubidium acetate); (C₂H₃O₂)Rb; [563-67-7]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied twice by Diogenov's group, as a side of the ternary C₂H₃O₂/Cs, Li, Rb (Ref. 1), and as a side of the reciprocal ternary C₂H₃O₂, NO₃/Li, Rb (Ref. 2), respectively.</p> <p>In both papers two eutectics are reported, viz., E₁ at 509 K (236 °C), and either 100x₁ = 88.5 (Ref. 1), or 100x₁ = 88 (Ref. 2), and E₂ at either 449 K (176 °C; Ref. 1), or 460 K (187 °C; Ref. 2), and 100x₁ = 26.</p> <p>In Ref. 1, however, Diogenov and Sarapulova report two intermediate compounds, i.e., (C₂H₃O₂)₅Li₂Rb₃ and (C₂H₃O₂)₅Li₃Rb₂ [congruently melting at 518 K (245 °C) and 582 K (309 °C), respectively], and consequently a third invariant, whilst Diogenov et al. report in Ref. 2 a single intermediate compound, (C₂H₃O₂)₃Li₂Rb [congruently melting at 573 K (300 °C)].</p> <p>Due to the detailed experimental evidence (obtained, inter alia, with X-ray diffractometry) given in Ref. 2, the evaluator thinks that the existence of the latter compound should be considered as reasonably assessed. On the contrary, the existence of both (C₂H₃O₂)₅Li₂Rb₃ and (C₂H₃O₂)₅Li₃Rb₂ does not seem adequately supported.</p> <p>It is to be noticed that some discrepancies exist between the phase transition temperatures reported in Ref. 2 and those given in Table 1 of the Preface, viz., T_{fus}(1) = 564 K (291 °C), to be identified with 557±2 K, T_{trs}(1) = 405 K (132 °C), with no correspondence, T_{fus}(2) = 509 K (236 °C), to be identified with 514±1 K, and T_{trs}(2) = 479 K (206 °C), to be identified with 498±1 K. These discrepancies, however, do not imply significant changes in the liquidus by Diogenov et al. (Ref. 2): the evaluator is consequently inclined to consider the presentation by these authors as sufficiently reliable.</p>

<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis as well as time-temperature curves were employed. The temperatures were measured with a Chromel-Alumel thermocouple checked at the freezing temperatures of Zn, $K_2Cr_2O_7$, Cd, Sn, and benzoic acid.</p> <p>NOTE:</p> <p>The formation of glasses in this system is reasonable. Accordingly, one should expect a marked tendency of the molten mixtures to supercool, which might cause the polythermal observations to be less reliable than usual.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: either ($C_2H_3O_2$)Li·2H₂O of analytical purity, or material obtained by reacting Li_2CO_3 and ethanoic acid; both materials dehydrated in an oven at 105-110 °C.</p> <p>Component 2: ($C_2H_3O_2$)₂Zn·2H₂O of analytical purity dried to constant mass at 110 °C.</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p> <p>REFERENCES:</p>

<p>COMPONENTS:</p> <p>(1) Magnesium ethanoate (magnesium acetate); ($C_2H_3O_2$)₂Mg; [142-72-3]</p> <p>(2) Sodium ethanoate (sodium acetate); ($C_2H_3O_2$)₂Na₂; [127-09-3]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system has been investigated only by Pochtakova (Ref. 1) who reports the results of visual polythermal observations supplemented with DTA investigations, both in numerical and graphical form.</p> <p>The trend of the accessible part of the liquidus ($0 \leq 100x_1 \leq 70$) has been interpreted by the author as follows: the occurrence of the intermediate compound ($C_2H_3O_2$)₄MgNa₂, congruently melting at 533 K (260 °C), splits the diagram into two eutectic subsystems whose invariants are E₁, at 529 K (256 °C) and $100x_2 = 40.0$, and E₂, at 528 K (255 °C) and $100x_2 = 57.5$. The author suggests also that the intermediate compound undergoes an alpha-beta transition at 493 K (220 °C), and a lattice readjustment of the beta form at 373 K (100 °C).</p> <p>For an evaluation of the reliability of the above conclusions, the following discrepancies between the text or tables and the original plot must be mentioned.</p> <p>(i) In the experimental section of the paper two solid-solid transitions are reported for component 1 at 425 K (152 °C) and 449 K (176 °C), respectively, whilst the corresponding figures on the plot are 425 K (152 °C) and 445 K (172 °C).</p> <p>(ii) The table summarizing the visual polythermal data reports two temperature values at $100x_1 = 50$, the first of which - possibly due to a misprint - probably corresponds to $100x_1 = 30$.</p> <p>(iii) The table collecting the DTA results reports, at $100x_1 = 60$, five temperature values, one of which (236 °C) is neither included in the phase diagram nor otherwise discussed in the text.</p> <p>(iv) No DTA evidence for the lattice readjustment at 373 K is provided at the composition of the intermediate compound.</p> <p>(v) DTA measurements carried out at $100x_2 > 50$ did not allow the author to obtain evidence for either the transition of the intermediate compound at 493 K, or the lattice readjustment at 373 K.</p> <p>(vi) DTA measurements carried out on the mixtures did not allow the author to obtain evidence for the solid state transitions of the pure components. It is however to be stressed that the transition temperatures of sodium ethanoate are quoted by the author from Ref. 2.</p> <p>In conclusion the upper part of the phase diagram given in the paper seems to be supported adequately by the experimental results, whereas the system is still to be considered as largely unexplored below the eutectic lines.</p> <p>REFERENCES:</p> <p>(1) Pochtakova, E.I. Zh. Obshch. Khim. <u>1974</u>, 44, 241-248.</p> <p>(2) Sokolov, N.M. Tezisy Dokl. X Nauchn. Konf. S.M.I. <u>1956</u>.</p>

<p>COMPONENTS:</p> <p>(1) Sodium ethanoate (sodium acetate); ($C_2H_3O_2$)Na; [127-09-3] (2) Rubidium ethanoate (rubidium acetate); ($C_2H_3O_2$)Rb; [563-67-7]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p>	
<p>This system was studied twice in Gimel'shtein's laboratory [Ref. 1: visual polythermal analysis (empty circles in the figure); Ref. 2: DTA (filled circles in the figure)] with substantially analogous results for the liquidus: an intermediate compound, $(C_2H_3O_2)_4NaRb_3$, congruently melting at 452-453 K (179 °C, Ref. 1; 180 °C, Ref. 2), forms eutectics with both pure components, at 418-419 K (145-146 °C) and $100x_1 = 38-38.5$, and at 451-453 K (178-180 °C) and $100x_1 = 23.5$, respectively.</p>	
<p>Discrepancies, however, exist between Ref.s 1 and 2 about the phase transition temperatures of the pure components.</p>	
<p>As for component 1, Gimel'shtein and Diogenov (Ref. 1) report $T_{trs}(1) = 583-584$ K (310-311 °C), while Gimel'shtein (Ref. 2) gives $T_{trs}(1) = 543$ K (270 °C). The former figure exceeds largely the highest $T_{trs}(1)$ value listed in Table 1 of the Preface, viz., 527±15 K, while the latter one lies just above the upper uncertainty limit of Table 1 value.</p>	
<p>As for component 2, 493 K (220 °C) and 479 K (206 °C) are reported in Ref. 1 and Ref. 2, respectively, as the transition temperature: the former value is close to, while the latter one is significantly lower than that listed in Table 1 of the Preface, viz., 498±1 K.</p>	
<p>X-ray diffractometric results were claimed (Ref. 2) to support the existence of the intermediate compound, and to suggest that this should decompose into a solid solution just below 383 K (110 °C). The second assertion, however, does not seem convincing, inasmuch as it would imply a change in the solid from a state of miscibility at lower temperatures into a state of immiscibility at higher temperatures.</p>	
<p>Finally, the assumption of the congruent fusion of the intermediate compound does not seem adequately supported: the shape of the liquidus could as well suggest the occurrence of a peritectic equilibrium, e.g., in connection with the incongruent fusion of the compound.</p>

COMPONENTS:

- (1) Sodium ethanoate (sodium acetate);
 $(C_2H_3O_2)Na$; [127-09-3]
 (2) Zinc ethanoate (zinc acetate);
 $(C_2H_3O_2)_2Zn$; [557-34-6]

EVALUATOR:

Schiraldi, A.,
 Dipartimento di Chimica Fisica,
 Universita' di Pavia (ITALY).

CRITICAL EVALUATION:

This system was studied by Lehrman and Skell (Ref. 1), Pavlov and Golubkova (Ref. 2), and Nadirov and Bakeev (Ref. 3).

A qualitative agreement exists between Refs. 1 and 2, as both of them report a phase diagram characterized by two eutectics, E_1 and E_2 , and the congruently melting intermediate compound $(C_2H_3O_2)_4Na_2Zn$. Differences between these papers concern the coordinates of the eutectics: according to Ref. 1, E_1 should occur at 491-493 K (218-220 °C) and $100x_2$ about 28, and E_2 at 548.5-551.8 K (175.3-178.6 °C) and $100x_2$ about 54, whereas, according to Ref. 2, the invariants should be at 473 K (200 °C) and $100x_2=25$, and at 413 K (140 °C) and $100x_2=50$, respectively.

The phase diagram suggested in Ref. 3 shows in turn: (i) a single eutectic at either 415, or 421 K (either 142, or 148 °C, according to visual polythermal and conductometric investigations, respectively) and $100x_2=57$; (ii) a peritectic at either 480, or 477, or 484 K (either 207, or 204, or 211 °C, according to visual polythermal, conductometric, and thermographical results, respectively), and, possibly, $100x_2=33.3$; and (iii) the intermediate compound $(C_2H_3O_2)_4Na_2Zn$ reported here as incongruently melting.

In the evaluator's opinion, the discrepancies among the diagrams suggested by the different authors should be attributed mainly to different degrees of accuracy in the determination of the actual liquidus temperatures. In this connection, it is important to stress that Lehrman and Skell observed a tendency of the melts to supercool and, in particular, found at temperatures below 483 K extremely viscous melts "so that great difficulty was experienced in obtaining crystallization and reproducible melting points" (Ref. 1). Consequently, in the case of the present binary, poorly reliable results can be reasonably expected both by techniques implying observations performed on cooling (as visual polythermal analysis), and by techniques (as conductometry) implying observations performed on heating at constant rate. Accordingly, the diagrams by Pavlov and Golubkova (based only on visual polythermal observations), and by Nadirov and Bakeev (based mainly on visual polythermal and conductometric investigations) probably suffer from limited accuracy.

In conclusion, the evaluator is inclined to consider as more reliable the findings by Lehrman and Skell (who employed very small heating rates), viz.: (i) the presence of the intermediate compound $(C_2H_3O_2)_4Na_2Zn$, congruently melting at about 500 K; and (ii) the occurrence of two eutectics, E_1 at about 490 K and $100x_2$ about 28, and E_2 at about 550 K and $100x_2$ about 54.

VARIABLES: Temperature.	PREPARED BY: Baldini, P.
EXPERIMENTAL VALUES: <div style="text-align: center;"> </div> <p>The results are reported only in graphical form (see figure).</p> <p>Characteristic point(s):</p> <p>Eutectic, E_1, at 200 °C and $100x_2 = 25$ (authors). Eutectic, E_2, at 140 °C and $100x_2 = 50$ (authors).</p> <p>Intermediate compound(s):</p> <p>$(C_2H_3O_2)_4Na_2Zn$, congruently melting at 240 °C (authors).</p>	
AUXILIARY INFORMATION	
METHOD/Apparatus/Procedure: Visual polythermal analysis as well as time-temperature curves were employed. The temperatures were measured with a Chromel-Alumel thermocouple checked at the freezing temperatures of Zn, $K_2Cr_2O_7$, Cd, Sn, and benzoic acid.	SOURCE AND PURITY OF MATERIALS: Component 1: $(C_2H_3O_2)Na \cdot 3H_2O$ of analytical purity recrystallized from water and dried in an oven at 110-120 °C to constant mass. Component 2: $(C_2H_3O_2)_2Zn \cdot 2H_2O$ of analytical purity dried to constant mass at 110 °C.
ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).

<p>AUXILIARY INFORMATION</p>																																																																																																							
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis, supplemented with differential thermal analysis.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Materials prepared (Ref. 1) by reacting the proper ("chemically pure") carbonate with a slight excess of propanoic acid of analytical purity. Component 1 undergoes phase transitions at $t_{trs}(1)/^{\circ}C = 68, 330$ (Ref. 2). Component 2 undergoes phase transitions at $t_{trs}(2)/^{\circ}C = 185, 200, 217, 246$.</p>																																																																																																						
<p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. Khim. <u>1954</u>, 24, 1581-1593.</p> <p>(2) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. <u>1956</u>.</p> <p>(3) Sanesi, M.; Cingolani, A.; Tonelli, P.L.; Franzosini, P.; Thermal Properties, in Thermodynamic and Transport Properties of Organic Salts, IUPAC Chemical Data Series No.28 (Franzosini, P.; Sanesi, M.; Editors), Pergamon Press, Oxford, <u>1980</u>, 29-115.</p>	<p>NOTES:</p> <p>The system was investigated at $0 < 100x_2 < 55$ due to thermal instability of component 2. The fusion temperature of component 1 is in fair agreement with that listed in Preface, Table 1, whereas discrepancies exist for the solid state transition temperatures of the same component. Moreover, it is worth mentioning that Pochtakova's paper is the only source of information (see Ref. 3) for what concerns the solid state transitions of magnesium propanoate.</p>																																																																																																						
<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																																																																																							

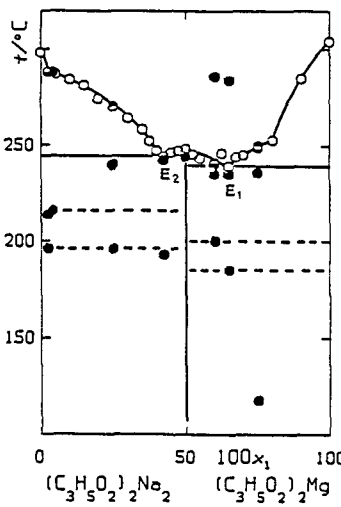

<p>COMPONENTS:</p> <p>(1) Potassium propanoate (potassium propionate); (C₃H₅O₂)K; [327-62-8]</p> <p>(2) Sodium propanoate (sodium propionate); (C₃H₅O₂)Na; [137-40-6]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied by visual polythermal analysis in Sokolov's laboratory as a side system of two reciprocal ternaries [i.e., K, Na/C₂H₃O₂, C₃H₅O₂ (Ref. 1), and K, Na/C₃H₅O₂, NO₃ (Ref. 2)] with almost identical results.</p> <p>The occurrence of eutectics at 583-585 K (310-312 °C) and 100x₁ = 66, and at 560-561 K (287-288 °C) and 100x₁ = 8 is to be held for certain, as well as the existence of a congruently melting intermediate compound. However, the composition of the latter as claimed by the authors [i.e., (C₃H₅O₂)₅K₃Na₂], although possible, does not seem fully proved due to the fluctuation of the experimental points, and the lack of data other than the visual polythermal ones.</p> <p>The fusion temperature of component 1 (638 K) is in fair agreement with that (638.3±0.5 K) listed in Table 1 of the Preface, whereas the fusion temperature of component 2 (571 K) has to be considered as too high, inasmuch as the DSC value given in Table 1 of the Preface, (562.4±0.2 K) was subsequently confirmed by that obtained with adiabatic calorimetry (561.88±0.03 K; Table 3).</p> <p>Rather puzzlingly, for the solid state transition temperature of component 1 far different values are quoted [from the same source (Ref. 3)] in Ref. 1 and Ref. 2, i.e., 603 and 341 K, respectively. Both figures are in turn different from that reported in Table 1 of the Preface (352.5±0.5 K).</p> <p>Again from Ref. 3, solid state transitions are quoted in both Ref. 1 and Ref. 2 as occurring in component 2 at T_{trs}(2)/K = 350, 468, 490, and 560. Doubts, however, are to be cast about the existence of the lowest transition as well as of the highest one, inasmuch as DSC provided evidence for the occurrence of only two solid state transformations (at 470.2±0.5 and 494±1 K, respectively; Preface, Table 1) which was subsequently confirmed with adiabatic calorimetry (Preface, Table 3).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Pochtakova, E.I. Zh. Obshch. Khim. 1958, 28, 1397-1404.</p> <p>(2) Dmitrevskaya, O.I.; Sokolov, N.M. Zh. Obshch. Khim. 1958, 28, 2920-2926 (*); Russ. J. Gen. Chem.(Engl. AUXILIARY INFORMATION																																																																									
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis. Temperature of initial crystallization measured with a Nichrome-Constantane thermocouple checked at the boiling point of water, and at the fusion points of benzoic acid, mannitol, succinic acid, silver nitrate, tin, potassium nitrate, and potassium dichromate. Mixtures melted in a glass tube inserted into a wider tube to ensure uniform heating. Glass fiber stirrer used.	SOURCE AND PURITY OF MATERIALS: Components prepared by adding a small excess of distilled commercial propanoic acid to a solution of the proper "chemically pure" hydrogen carbonate; the solids recovered after evaporation of the solvent were recrystallized from butanol. Component 1 undergoes a phase transition at $t_{trs}(1)/^\circ C = 68$ (Ref. 1). Component 2 undergoes phase transitions at $t_{trs}(2)/^\circ C = 77, 195, 217, 287$ (Ref. 1).

<p>COMPONENTS:</p> <p>(1) Magnesium propanoate (magnesium propionate); ($C_3H_5O_2$)₂Mg; [557-27-7]</p> <p>(2) Sodium propanoate (sodium propionate); ($C_3H_5O_2$)₂Na₂; [137-40-6]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied by Pochtakova (Ref. 1) both with visual polythermal and DTA investigation. In order to evaluate the trustworthiness of her results, the following points have to be considered.</p> <p>(i) The fusion temperature of component 1 (577 K) coincides with the DSC value by Ferloni et al. (Ref. 2).</p> <p>(ii) Pochtakova's solid state transition temperatures of the same component (i.e., 458, 473, 490, and 519 K) represent the only source of information on this subject.</p> <p>(iii) The fusion temperature of component 2 (571 K) has to be considered as too high, inasmuch as the DSC value (562.4±0.2 K) given in Preface, Table 1 was subsequently confirmed by that obtained with adiabatic calorimetry (561.88±0.03 K; Preface, Table 3).</p> <p>(iv) As for the solid state transitions of the same component quoted by Pochtakova from Ref. 3 as occurring at $T_{trs}(2)/K = 350, 468, 490, \text{ and } 560$, heavy doubts are to be cast about the existence of the lowest and highest ones inasmuch as DSC provided evidence for only two solid state transformations (at 470.2±0.5, and 494±1 K, respectively; Preface, Table 1) which was subsequently confirmed with adiabatic calorimetry (Preface, Table 3).</p> <p>(v) Indeed, the DTA traces recorded at $100x_1 = 2.5, 4, 25, \text{ and } 42.5$ seem to be consistent with the existence of only two solid state transitions of component 2; moreover, they support the occurrence of eutectic E_2, and tend to prove the absence of solid solutions between component 2 and the intermediate compound.</p> <p>(vi) The DTA traces recorded at $100x_1 = 60, 65, \text{ and } 75$ are somewhat embarrassing because all of them support the occurrence of eutectic E_1, but evidence for solid state transitions of component 1 is offered only by the trace taken at $100x_1 = 60$ for what concerns the transition at 473 K, and by that taken at $100x_1 = 65$ for what concerns the transition at 458 K.</p> <p>(vii) No explanation is given by the author for the discontinuities exhibited at temperatures far above the liquidus by the DTA traces taken at $100x_1 = 60, \text{ and } 65$.</p> <p>In conclusion, the evaluator is inclined to consider as satisfactorily supported by the experimental evidence:</p> <p>(i) the occurrence of the congruently melting intermediate compound ($C_3H_5O_2$)₄MgNa₂;</p> <p>(ii) the occurrence of eutectics E_1 and E_2, located as suggested by Pochtakova; and</p> <p>(iii) the phase relations relevant to solidus and subsolidus at $0 \leq 100x_1 \leq 50$ as suggested by Pochtakova.</p> <p>On the contrary, the knees occurring in the liquidus branch richest in component 1 as well as in that richest in component 2, the nature of possible transformations occurring in the melt, and the phase relations relevant to solidus and subsolidus at $50 \leq 100x_1 \leq 100$ seem to need further investigation.</p> <p>REFERENCES:</p> <p>(1) Pochtakova, E.I. Zh. Obshch. Khim. <u>1974</u>, <u>44</u>, 241-248.</p> <p>(2) Ferloni, P.; Sanesi, M.; Franzosini, P. Z. Naturforsch. <u>1976</u>, <u>31a</u>, 679-682.</p> <p>(3) Sokolov, N.M. Tezisy Dokl. X Nauch. <p>COMPONENTS:</p> <p>(1) Potassium butanoate (potassium butyrate); ($C_4H_7O_2$)₂K₂; [589-39-9]</p> <p>(2) Magnesium butanoate (magnesium butyrate); ($C_4H_7O_2$)₂Mg; [556-45-6]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied only by Pochtakova (Ref. 1) who, on the basis of her visual polythermal and DTA results, asserted the occurrence of a congruently melting intermediate compound, i.e., ($C_4H_7O_2$)₄K₂Mg, forming (possibly simple) eutectics with either component.</p> <p>Component 1, however, goes through the liquid crystalline state before transformation into a clear melt. Therefore, the topology of the phase diagram at $0 \leq 100x_2 \leq 50$ should be described more correctly with reference to Scheme B.1 of the Preface, and an invariant type M_p (undetected by Pochtakova) should also exist.</p> <p>The following points are still worth mentioning.</p> <p>(i) Pochtakova's fusion temperature of component 1 (677 K) coincides with the clearing temperature (677.3±0.5 K) listed in Preface, Table 1 for the same component, whereas her T_{fus}(2) value (575 K) is noticeably higher than data by other authors reported in Ref. 2.</p> <p>(ii) Among the phase transformation temperatures of component 1 quoted in Ref. 1 from Ref. 3 (i.e., 618, 553-558, and 463 K) the first one can be reasonably identified with the fusion temperature (626.1±0.7 K) listed in Preface, Table 1, whereas the second and third ones lie each halfway between the two pairs of solid state transition temperatures (i.e., 562.2±0.6 and 540.8±1.1, and 467.2±0.5 and 461.4±1.0, respectively) also reported in Table 1 of the Preface.</p> <p>(iii) No explanation is given by the author for the discontinuities observed at temperatures (643 and 624 K, respectively) far above the liquidus in the DTA traces taken at 100x₂ = 25 and 50.</p> <p>(iv) The author's explanation, that the discontinuities observed at temperatures corresponding to the lowest section of the subsolidus might be due to transformation (at about 445 K) of the intermediate compound into a metastable phase turning to stable at 370-400 K, should be more detailed and better supported.</p> <p>In conclusion it seems to the evaluator that the composition of the intermediate compound, the location of both eutectics, the liquidus dome, and the liquidus branch richest in component 2 are sufficiently well assessed, whereas the remaining part of the diagram needs several refinements to become satisfactory.</p> <p>REFERENCES:</p> <p>(1) Pochtakova, E.I. COMPONENTS:

- (1) Potassium butanoate (potassium butyrate);
($C_4H_7O_2$)K; [589-39-9]
(2) Sodium butanoate (sodium butyrate);
($C_4H_7O_2$)Na; [156-54-7]

EVALUATOR:

Franzosini, P.,
Dipartimento di Chimica Fisica
Universita' di Pavia (ITALY).

CRITICAL EVALUATION:

The visual polythermal method was employed by Sokolov and Pochtakova (Ref. 1), and by Dmitrevskaya (Ref. 2) to study the lower boundary of the isotropic liquid field: according to these authors, continuous series of solid solutions ought to exist.

Both components, however, form liquid crystals. Consequently: (i) the fusion temperatures, $T_{\text{fus}}(1) = 677 \text{ K}$ ($404 \text{ }^\circ\text{C}$) and $T_{\text{fus}}(2) = 603 \text{ K}$ ($330 \text{ }^\circ\text{C}$), reported in Refs. 1, 2 should be identified with the clearing temperatures; and (ii) a continuous series of liquid crystal (and not of solid) solutions should be expected.

More recently, Prisyazhnyi et al. (Ref. 3) - to whom Refs. 1, 2 seem to be unknown - carried out a derivatographical re-investigation of the system, which allowed them to draw the lower boundaries of both the isotropic liquid, and the liquid crystal field. Their clearing [678 K ($405 \text{ }^\circ\text{C}$); 595 K ($322 \text{ }^\circ\text{C}$)] and fusion [628 K ($355 \text{ }^\circ\text{C}$); 523 K ($250 \text{ }^\circ\text{C}$)] temperatures substantially agree with the corresponding values from Preface, Table 1 (677.3 ± 0.5 , 600.4 ± 0.2 , and 626.1 ± 0.7 , $524.5 \pm 0.5 \text{ K}$, respectively).

Prisyazhnyi et al.'s, and Dmitrevskaya's results (filled and empty circles, respectively) are compared in the figure (IL: isotropic liquid; LC: liquid crystals). The complete phase diagram ought to be similar to that reported in Scheme C.1, and the only invariant ought to be classified as an M_E point, at which equilibrium occurs among one liquid crystalline and two solid phases. The statements made in Refs. 1, 2 cannot be considered as correct, whereas Prisyazhnyi et al.'s measurements look as compatible with expectation.

The latter measurements can be further commented as follows: (i) the two-phase region pertinent to the liquid crystal - isotropic liquid equilibria might be so narrow as to prevent observation of two distinct sets of points in this region; (ii) the lack of information about eutectic fusion in the different samples submitted to derivatographical analysis remains, however, rather surprising.

(continued in the next page)

<p>COMPONENTS:</p> <p>(1) Potassium butanoate (potassium butyrate); (C₄H₇O₂)K; [589-39-9]</p> <p>(2) Sodium butanoate (sodium butyrate); (C₄H₇O₂)Na; [156-54-7]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION: (continued)</p> <p>Finally, the following two points deserve attention.</p> <p>(i) Among the phase transformation temperatures of component 1 quoted in Refs. 1, 2 from Ref. 4 (i.e., 618, 553-558, and 463 K) the first one can be reasonably identified with the fusion temperature (626.1±0.7 K) listed in Preface, Table 1, whereas the second and third ones lie each halfway between the two pairs of solid state transition temperatures (i.e., 562.2±0.6 and 540.8±1.1, and 467.2±0.5 and 461.4±1.0, respectively) also reported in Table 1 of the Preface.</p> <p>(ii) For component 2, Table 1 of the Preface [besides the clearing temperature] provides solid state transitions at 450.4±0.5, 489.8±0.2, 498.3±0.3, and 508.4±0.5, and fusion at 524.5±0.5. It is to be stressed that these phase relations, first stated on the basis of DSC records, were subsequently confirmed by Schiraldi and Chiodelli's conductometric results (Ref. 5). On the other hand, phase transformations are quoted in Refs. 1, 2 from Ref. 4 as occurring at 390, 505, 525, and 589 K, respectively. A comparison of the two sets of data allows one to identify conveniently the two intermediate transition temperatures from Ref. 4 with the first transition temperature and the fusion temperature from Table 1, whereas reasonable doubts can be cast about the actual existence of the highest and lowest transformations quoted in Refs. 1, 2.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Pochtakova, E.I. CRITICAL EVALUATION:

The visual polythermal analysis was employed by Tsindrik and Sokolov (Ref. 1) to study the lower boundary of the isotropic liquid field: according to these authors, a eutectic ought to exist at 495 K (222 °C), and $100x_2 = 50$.

Component 2, however, forms liquid crystals. Consequently: (i) the fusion temperature, 603 K (330 °C) reported in Ref. 1 should be identified with the clearing temperature; (ii) the two branches of the curve refer to equilibria of different kind; and (iii) the intersection of the two branches cannot be classified as a eutectic.

More recently, Prisyazhnyi et al. (Ref. 2) - to whom Ref. 1 seems to be unknown - carried out a derivatographical re-investigation of the system, which allowed them to draw the lower boundaries of both the isotropic liquid, and the liquid crystal field. Their clearing [$T_{clr}(2) = 595$ K (322 °C)] and fusion [$T_{fus}(1) = 598$ K (325 °C); $T_{fus}(2) = 524$ K (251 °C)] temperatures substantially agree with the corresponding values from Table 1 of the Preface (600.4±0.2; 591.7±0.5, and 524.5±0.5 K, respectively).

Prisyazhnyi et al.'s, and Tsindrik and Sokolov's results (filled and empty circles, respectively) are compared in the figure (IL: isotropic liquid; LC: liquid crystals). Assuming that limited solid solutions are present, the complete phase diagram ought to be similar to that reported in Preface, Scheme A.1. The upper invariant ought to be classified as an M'_E point, and the lower one as an M_E point.

Prisyazhnyi et al.'s measurements look as compatible with expectation, although the lack of information about eutectic fusion in the different samples studied by derivatographical analysis remains rather surprising. Instead, the narrowness of the two-phase region pertinent to the liquid crystal - isotropic liquid equilibria could have prevented the observation of two distinct sets of points in this region.

Finally, the following point requires attention. For component 2, Table 1 of the Preface [besides the $T_{clr}(2)$ value] provides four solid state transitions at 450.4±0.5, 489.8±0.2, 498.3±0.3, and 508.4±0.5 K, and $T_{fus}(2)/K = 524.5±0.5$. It is to be stressed that these phase relations, first stated on the basis of DSC records, were subsequently confirmed by Schiraldi and Chiodelli's conductometric results (Ref. 3). On the other hand, phase transformations are quoted in Ref. 1 from Ref. 4 as occurring at 390, 505, 525, and 589 K, respectively. A comparison of the two sets of data allows one to identify conveniently the two intermediate transition temperatures from Ref. 4 with the first solid state transition and fusion temperatures from Table 1 of the Preface, whereas reasonable doubts can be cast about the actual existence of the highest and lowest transformations quoted in Ref. 1.

<p>CRITICAL EVALUATION:</p> <p>This binary was studied only by Pochtakova (Ref. 1) who (on the basis of visual polythermal and DTA results) claimed the occurrence of the congruently melting intermediate compound $(C_4H_7O_2)_7 Mg_2Na_3$, able to give eutectics with either component.</p> <p>Component 2, however, goes through the liquid crystalline state before transformation into a clear melt. Therefore the topology of the phase diagram at $0 < 100x_1 < 57$ should be described more correctly with (probable) reference to Preface, Scheme A.1: in this case the invariant ought to be of the M_E type.</p> <p>The following points are still worth mentioning.</p> <p>(i) Pochtakova's fusion temperature of component 1 (575 K) is noticeably higher than data by other authors reported in Ref. 2, whereas her $T_{fus}(2)$ value (603 K) is in reasonable agreement with the clearing temperature (600.4 ± 0.2 K) listed in Preface, Table 1 for component 2.</p> <p>(ii) Again for component 2, Table 1 of the Preface provides four transition temperatures (450.4 ± 0.5, 489.8 ± 0.2, 498.3 ± 0.3, and 508.4 ± 0.5 K), and $T_{fus}(2)/K = 524.5 \pm 0.5$. It is to be stressed that these phase relations, first stated on the basis of DSC records, were subsequently confirmed by Schiraldi and Chiodelli's conductometric results (Ref. 3). On the other hand, phase transformations are quoted in Ref. 1 from Ref. 4 as occurring at 390, 505, 525, and 589 K, respectively. A comparison of the two sets of data allows one to identify conveniently the two intermediate transition temperatures from Ref. 4 with the highest solid state transition and fusion, respectively, from Table 1 of the Preface, whereas reasonable doubts can be cast about the actual existence of the highest and lowest transformations quoted by Pochtakova.</p> <p>(iii) In the DTA traces taken at $100x_1 = 10$ and 35, Pochtakova observed discontinuities at 587 and 573 K, and at 528 and 507 K, respectively, which might correspond to the higher (587 and 528 K) and lower (573 and 507 K) boundary of a diphasic region, thus supporting an interpretation of the phase diagram based on Scheme A.1 of the Preface.</p> <p>(iv) The author's explanation, that the discontinuities observed at temperatures corresponding to the lowest section of the subsolidus might be due to the transformation (at about 435 K) of the intermediate compound into a metastable phase turning to stable at about 410 K, should be more detailed and better supported.</p> <p>In conclusion, it seems to the evaluator that the existence of an intermediate compound, the location of both eutectics, and the liquidus branch richest in component 1 are sufficiently well assessed, whereas other parts of the diagram need refinements.</p> <p>REFERENCES:</p> <p>(1) Pochtakova, E.I. <p>COMPONENTS:</p> <p>(1) Potassium iso.butanoate (potassium iso.butyrate); ($i\text{-C}_4\text{H}_7\text{O}_2$)K; [19455-20-0]</p> <p>(2) Sodium iso.butanoate (sodium iso.butyrate); ($i\text{-C}_4\text{H}_7\text{O}_2$)Na; [996-30-5]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov and Pochtakova (Ref. 1) who suggested the phase diagram to be of the eutectic type, the invariant point occurring at 521 K (248 °C) and $100x_1 = 7.5$.</p> <p>Component 1, however, forms liquid crystals. Therefore the temperature of 633 K (360 °C) given in Ref. 1 should be identified with the clearing (and not the fusion) temperature of this component, and compared with the $T_{\text{clr}}(1)$ value (625.6 ± 0.8 K) reported in Table 2.</p> <p>For the same component, three phase transition temperatures are quoted in Ref. 1 from Ref. 2, i.e., 621, 546, and 481 K, the second of which can be reasonably identified with the fusion temperature [$T_{\text{fus}}(1) = 553.9 \pm 0.5$ K] listed in Preface, Table 2. Consequently: (i) the transition temperature at 621 K (if actually existing) might correspond to some kind of transformation (undetected by DSC, see Preface, Table 2) within the liquid crystal field; and (ii) only the transition at 481 K should correspond to a solid state transformation, although the latter figure is almost 60 K higher than the single $T_{\text{trs}}(1)$ value (424 ± 3 K) listed in Table 2 of the Preface.</p> <p>Concerning component 2, the fusion temperature of 535 K (262 °C; Ref. 1) is in reasonable agreement with that (526.9 ± 0.7 K) reported in Table 2 of the Preface. In this Table, however, no mention is made of other phase transformations, although three solid state transitions are quoted for this component in Ref. 1 (from Ref. 2), at 493, 364, and 340 K (220, 91, and 67 °C), respectively. Duruz et al. (Ref. 3) report in turn: fusion at 527 K (in agreement with the fusion temperature from Table 2), and solid state transitions at 493 K (in agreement with the highest transition temperature from Ref. 2), and at 468 K (a figure which has no correspondence in Ref. 2). Finally, Ferloni et al. (Ref. 4) are inclined to think that Sokolov's transformation at 340 K (Ref. 2) actually represents a transition of a hydrated form of the salt.</p> <p>In the evaluator's opinion, a re-investigation of the phase relations in solid sodium iso.butanoate would be desirable. At any rate, the phase diagram suggested by Sokolov and Pochtakova (Ref. 1) has to be modified (due to the occurrence of liquid crystals in component 1) with reference to Schemes A.1, or A.3, of the Preface according to the kind of solid state miscibility between components, the eutectic point actually being an M'_E point.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Pochtakova, E.I. <p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Both components were prepared from commercial "pure" grade iso.butanoic acid, distilled before use, and the proper "chemically pure" hydrogen carbonate (Ref. 1); then recrystallized from n-butanol. Component 1 undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 208, 273, 348$ (Ref. 2). Component 2 undergoes phase transitions at $t_{\text{trs}}(2)/^\circ\text{C} = 67, 91, 220$ (Ref. 2).</p>																																																																					
<p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. Khim. 1954, 24, 1150-1156.</p> <p>(2) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956 (this is Ref. 6 in the original paper, and not Ref. 5 as erroneously quoted in the text; compiler).</p>	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																																																					

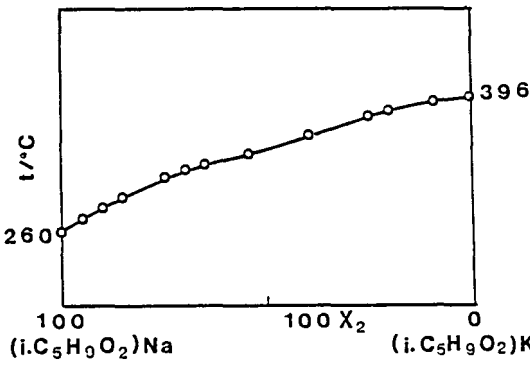

<p>COMPONENTS:</p> <p>(1) Potassium pentanoate (potassium valerate); (C₅H₉O₂)K; [19455-21-1]</p> <p>(2) Sodium pentanoate (sodium valerate); (C₅H₉O₂)Na; [6106-41-8]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Dmitrevskaya and Sokolov (Ref. 1), who claimed that continuous series of solid solutions exist.</p> <p>Both components, however, form liquid crystals (see Preface, Table 1). Consequently: (i) the fusion temperatures, $T_{fus}(1) = 717 \text{ K (} 444 \text{ }^\circ\text{C)}$ and $T_{fus}(2) = 630 \text{ K (} 357 \text{ }^\circ\text{C)}$ given in Ref. 1, are actually to be identified with the clearing temperatures (the corresponding values from Preface, Table 1 being $716 \pm 2 \text{ K}$ and $631 \pm 4 \text{ K}$, respectively); (ii) the transition temperatures $T_{trs}(1) = 580 \text{ K (} 307 \text{ }^\circ\text{C)}$ and $T_{trs}(2) = 489 \text{ K (} 216 \text{ }^\circ\text{C)}$ quoted in Ref. 1 from Ref. 2, are in turn to be identified with the actual fusion temperatures (the corresponding values from Table 1 of the Preface being $586.6 \pm 0.7 \text{ K}$ and $498 \pm 2 \text{ K}$, respectively).</p> <p>Continuous series of liquid crystal (instead of solid) solutions ought to form, and the phase diagram ought to be similar to that shown in Preface, Scheme C.1.</p> <p>Moreover, the following point deserves attention. For component 2, Table 1 of the Preface reports no solid state transition, whereas Dmitrevskaya and Sokolov quote (again from Ref. 2) $T_{trs}(2)/\text{K} = 482$ and 453. It is, however, to be stressed that the single transition observed (at $479 \pm 1 \text{ K}$) with DTA in sodium n-pentanoate by Duruz et al. (Ref. 3) was not more mentioned in a subsequent DSC investigation by the same group (Ref. 4).</p> <p>In conclusion, due to the lack of information about the boundaries of the mesomorphic liquid field, and to conflicting assertions about solid state transitions, a re-investigation of the system would be desirable.</p> <p>REFERENCES:</p> <p>(1) Dmitrevskaya, O.I.; Sokolov, N.M. <p>COMPONENTS:</p> <p>(1) Magnesium pentanoate (magnesium valerate); ($C_5H_9O_2$)₂Mg; [556-37-6]</p> <p>(2) Sodium pentanoate (sodium valerate); ($C_5H_9O_2$)₂Na₂; [6106-41-8]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied only by Pochtakova (Ref. 1) who employed the visual polythermal analysis to draw the lower boundary of the isotropic liquid region at $0 < 100x_1 < 72.5$ (the investigation of mixtures richer in component 1 being prevented by their tendency to form glasses). She claimed the occurrence of an incongruently melting intermediate compound, i.e., ($C_5H_9O_2$)₈Mg₃Na₂, able to give a eutectic with component 2.</p> <p>The latter component, however, forms liquid crystals. Consequently, the topology of the phase diagram at $0 < 100x_1 < 55$ could be described more correctly with (possible) reference to Scheme D.1 of the Preface: accordingly, Pochtakova's eutectic ought to be an M_E^r point, and an invariant type M_E (undetected by visual polythermal analysis) ought to exist at $100x_1 < 55$.</p> <p>A few more points are worth mentioning.</p> <p>(i) Pochtakova's (extrapolated) fusion temperature of component 1 (537 K) seems reasonable, although somewhat higher than the only other value provided by the literature (531 K; Ref. 2), while her $T_{fus}(2)$ value (630 K) agrees fairly with the clearing temperature (631+4 K) listed in Preface, Table 1 for component 2.</p> <p>(ii) For the same component, Table 1 of the Preface provides also a $T_{fus}(2) = 498 \pm 2$ K, a figure which can be identified (even if not fully satisfactorily) with that (489 K) corresponding to the highest phase transformation temperature quoted by Pochtakova from Ref. 3.</p> <p>(iii) Once more for component 2, Table 1 of the Preface reports no solid state transition, whereas Pochtakova quotes (from Ref. 3) $T_{trs}(2)/K = 482$ and 453. It is, however, to be stressed that the single transition observed (at 479+1 K) with DTA in sodium n-pentanoate by Duruz et al. (Ref. 4) was not more mentioned in a subsequent DSC investigation by the same group (Ref. 5).</p> <p>In conclusion, due to the lack of information about the boundaries of the mesomorphic liquid field, and to conflicting assertions about solid state transitions, a re-investigation of the system would be desirable.</p>

<p>COMPONENTS:</p> <p>(1) Potassium iso.pentanoate (potassium iso.valerate); ($i.C_5H_9O_2$)K; [589-46-8]</p> <p>(2) Sodium iso.pentanoate (sodium iso.valerate); ($i.C_5H_9O_2$)Na; [539-66-2]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied by Pochtakova (Ref. 1), and by Dmitrevskaya and Sokolov (Ref. 2): according to both papers, continuous series of solid solutions ought to be formed.</p> <p>Both components, however, form liquid crystals (see Preface, Table 2). Consequently the fusion temperatures, $T_{fus}(1) = 669$ K (396 °C; Refs. 1, 2), and $T_{fus}(2) = 533$ K (260 °C; Ref. 1) or 535 K (262 °C; Ref. 2), are actually to be identified with the clearing temperatures, the corresponding values from Table 2 of the Preface being 679±2 K and 559±1 K, respectively. The latter figure is remarkably higher than those given by the Russian authors, although meeting rather satisfactorily those reported by Ubbelohde et al. (556 K; Ref. 3) and by Duruz et al. (553 K; Ref. 4).</p> <p>No mention is made in Refs. 1, 2 of the actual fusion of component 1 which occurs at 531±3 K (Table 2): the latter figure is supported by the trend of the thermomagnetical curves plotted by Duruz and Ubbelohde (Ref. 5). As for the other phase transitions of the same component, Pochtakova quotes from Ref. 6 two T_{trs} values, i.e., 327 and 618 K (54 and 345 °C, respectively), for which no comparison is possible with the findings by other investigators, inasmuch as: (i) no transformation is reported in Table 2 as occurring below $T_{fus}(1) = 531±3$ K; and (ii) no transformation is reported in Table 2 or in Ref. 5 as occurring within the field of existence of the mesomorphic liquid. It is a bit puzzling the fact that for potassium iso.pentanoate Dmitrevskaya and Sokolov (Ref. 2) quote from the same source (Ref. 6) transitions at 618, 493, and 473 K (ignoring that quoted by Pochtakova at 327 K).</p> <p>In the case of component 2, the transition at 451 K (178 °C; quoted in Refs. 1, 2 from Ref. 5) should be identified with the actual fusion temperature (the corresponding value from Table 2 of the Preface being 461.5±0.6 K).</p> <p>Taking into account the above remarks, the upper part of Dmitrevskaya and Sokolov's diagram, Ref. 2, (to be compared with the upper part of Preface, Scheme C.1) supports the idea that continuous series of liquid crystal (instead of solid) solutions do form. Moreover, the left-hand side of the lower part of the same diagram might suggest that, at lower temperatures, solid solutions are also present.</p> <p>REFERENCES:</p> <p>(1) Pochtakova, E.I. Zh. <p>COMPONENTS:</p> <p>(1) Potassium hexanoate (potassium caproate); (C₆H₁₁O₂)K; [19455-00-6]</p> <p>(2) Sodium hexanoate (sodium caproate); (C₆H₁₁O₂)Na; [10051-44-2]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Pochtakova (Ref. 1), who claimed the existence of a continuous series of solid solutions.</p> <p>Both components, however, form liquid crystals (see Preface, Table 1). Consequently: (i) the fusion temperatures, $T_{fus}(1) = 717.7$ K (444.5 °C) and $T_{fus}(2) = 638$ K (365 °C) given in Ref. 1 are actually to be identified with the clearing temperatures (the corresponding values from Table 1 of the Preface being 725.8 ± 0.8 K and 639.0 ± 0.5 K, respectively); (ii) the transition temperatures $T_{trs}(1) = 575$ K (302 °C) and $T_{trs}(2) = 499$ K (226 °C), quoted in Ref. 1 from Ref. 2, are in turn to be identified with the fusion temperatures (the corresponding values from Table 1 of the Preface being 581.7 ± 0.5 K and 499.6 ± 0.6 K).</p> <p>Finally, the following point deserves attention. Two more transitions are quoted in Ref. 1 from Ref. 2 as occurring in component 2 at 615 K (342 °C) and 476 K (203 °C), respectively. The latter one corresponds to that reported at 473 ± 2 K in Table 1 of the Preface, whereas no evidence was obtained by subsequent investigators (Ref. 3) for a transition comparable with the former one: should it exist, it might mean that two different mesomorphic phases are present in sodium hexanoate.</p> <p>As a conclusion, in the evaluator's opinion Pochtakova's data support reasonably the idea that continuous series of liquid crystal (instead of solid) solutions are formed, and the phase diagram ought to be not far from that shown in Preface, Scheme C.1.</p>

<p>EXPERIMENTAL VALUES:</p> <div style="text-align: center;">  <p>The graph plots the melting point t in degrees Celsius on the vertical axis against the composition $100 X_1$ on the horizontal axis. The vertical axis has tick marks at 365 and 444.5. The horizontal axis has tick marks at 0, 100, and 100. The data points, represented by small circles, form a smooth, upward-sloping curve. The curve starts at $t = 365$ when $100 X_1 = 0$ and ends at $t = 444.5$ when $100 X_1 = 100$. The labels $(C_6H_{11}O_2)Na$ and $(C_6H_{11}O_2)K$ are placed below the x-axis at the 0 and 100 positions, respectively.</p> </div> <p>The results are reported only in graphical form (see figure).</p> <p>Characteristic point(s): Continuous series of solid solutions.</p>

Thermal Properties, in Thermodynamic and Transport Properties of Organic Salts, IUPAC Chemical Data Series No. 28 (Franzosini, P.; Sanesi, M.; Editors), Pergamon Press, Oxford, <u>1980</u>, 29-115.</p>

<p>COMPONENTS:</p> <p>(1) Cesium ethanoate (cesium acetate); CsC₂H₃O₂; [3396-11-0]</p> <p>(2) Cesium nitrate; CsNO₃; [7789-18-6]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A. Dipartimento di Chimica fisica, Universita' di Pavia (ITALY)</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied with visual polythermal analysis by Nurminskii and Diogenov (as a side of the reciprocal ternary Cs, K/C₂H₃O₂, NO₃; Ref. 1), and by Gimel'shtein and Diogenov (as a side of the reciprocal ternary Cs, Na/C₂H₃O₂, NO₃; Ref. 2), with a substantially similar conclusion: the system is of the eutectic type, the invariant being at either 415 K (142 °C; Ref. 1), or 429 K (156 °C; Ref. 2), and 100x₂= 25 (Refs. 1,2).</p> <p>In Ref. 1 the authors claim also the existence of a phase transition of component 1 at 447 K (174 °C) whose existence, however, was neither mentioned in Ref. 2, nor confirmed by other investigators (Ref. 3).</p> <p>The fusion temperature of component 1 reported in both papers, i.e., 455 K (182 °C) represents the third lowest value among those listed in Ref. 3, which range between 453 and 467 K. It seems then likely that some impurity (possibly water) was present in the material used by Diogenov et al.</p> <p>In the evaluator's opinion, there is no reason to reject the assertion made in Refs. 1 and 2, that the diagram is of the eutectic type: however, due to the possibly inadequate purity of component 1, and to the large discrepancy in the eutectic temperature, a re-investigation of the system would be highly desirable.</p> <p>REFERENCES:</p> <p>(1) Nurminskii, N.N.; Diogenov, G.G. <p>AUXILIARY INFORMATION</p>																																																																			
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p> <p>NOTE:</p> <p>The fusion temperatures found by Sokolov are in reasonable agreement with those reported in Preface, Table 1 [$T_{fus}(1)=441.9\pm 0.5$ K, and $T_{fus}(2)=578.7\pm 0.5$ K]. Disagreement, on the contrary, exists about the number and location of the solid state transitions. As an example, for component 1 Table 1 of the Preface reports a single transition at a temperature (418±1 K) halfway between the highest (430 K) and second highest (408 K) values by Sokolov; the literature unfortunately provides no other data (Ref. 2).</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Not stated.</p> <p>Component 1 undergoes phase transitions at $t_{trs}(1)/^{\circ}C= 60, 135, 157$ (Ref. 1).</p> <p>Component 2 undergoes phase transitions at $t_{trs}(2)/^{\circ}C= 58, 150$ [Ref. 1; the figure 150, however, is probably a misprint, because in several other papers the same author, quoting the same source (unavailable to the compiler), reports the figure 155; compiler].</p>																																																																		
<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>	<p>REFERENCES:</p> <p>(1) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. COMPONENTS: (1) Potassium methanoate (potassium formate); KCHO_2 ; [590-29-4] (2) Potassium propanoate (potassium propionate); $\text{KC}_3\text{H}_5\text{O}_2$ [327-62-8]	ORIGINAL MEASUREMENTS: Sokolov, N.M.; Minchenko, S.P. <i>Zh. Obshch. Khim.</i> 1971, 41, 1656-1659.
VARIABLES: Temperature.	PREPARED BY: Baldini, P.
EXPERIMENTAL VALUES: <div style="text-align: center;"> </div> <p>The results are reported only in graphical form (see figure; empty circles: visual polythermal analysis; filled circles: thermographical analysis).</p> <p>Characteristic point(s): Eutectic, E, at 160 °C and $100x_2 = 5$ (authors).</p>	
AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis supplemented with thermographical analysis. NOTE: The fusion temperatures by Sokolov and Minchenko (440 and 638 K for components 1 and 2, respectively) almost coincide with those listed in Preface, Table 1 (respectively 441.9 ± 0.5 K and 638.3 ± 0.5 K). An approximate agreement exists also on the solid state transition of component 2. On the contrary, there is disagreement about solid state transitions of component 1, inasmuch as Table 1 of the Preface reports a single transformation at a temperature (418 ± 1) K halfway between the highest (430 K) and second highest (408 K) values by Sokolov and Minchenko; the literature, unfortunately, provides no other data (Ref. 3).	SOURCE AND PURITY OF MATERIALS: Component 1 (commercial material recrystallized from methanoic acid) melts at $t_{\text{fus}}(1)/^\circ\text{C} = 167$ and undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 60, 135, 157$ (Ref. 1). Component 2 (prepared from propanoic acid and carbonate, Ref.2) melts at 365 °C and undergoes a phase transition at 68 °C (Ref. 1).
ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).	REFERENCES: (1) Sokolov, N.M. <i>Tezisy Dokl. X Nauch. Konf. S.M.I.</i> 1956, (2) Sokolov, N.M. <i>Zh. Obshch. Khim.</i> 1954, 24, 1581-1593. <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Zh. Obshch. Khim. 1954, 24, 1581-1593.</p>	

<p>COMPONENTS:</p> <p>(1) Potassium methanoate (potassium formate); KCHO₂; [590-29-4]</p> <p>(2) Potassium iso.butanoate (potassium iso.butyrate); Kl.C₄H₇O₂ [19455-20-0]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied only by Sokolov and Minchenko (Ref. 1), who employed the visual polythermal analysis to outline the lower boundary of the isotropic liquid field, and claimed the existence of a single invariant, i.e., a eutectic at 437 K and 100x₂= 1.</p> <p>Component 2, however, forms liquid crystals. Therefore the topology of the phase diagram ought to be described more correctly with reference to Schemes B.1 or B.2 of the Preface, and an invariant type M^p (undetected by Sokolov and Minchenko) should also exist. Accordingly, the main branch of Sokolov and Minchenko's diagram should represent solid-liquid equilibria only at temperatures lower than that corresponding to M^p.</p> <p>It can be further noted that a reasonable agreement exists: (i) between the fusion temperature reported for component 1 in Ref. 1 (440 K) and in Preface, Table 1 (441.9+0.5 K); and (ii) between Sokolov and Minchenko's fusion temperature of component 2 (629 K) and the clearing temperature (625.6+0.8 K) listed in Table 2 of the Preface for the same component.</p> <p>Disagreement, on the contrary, exists about the remaining phase transformations. For component 1, Table 1 of the Preface reports a single solid state transition occurring at a temperature (418+1 K) halfway between the highest (430 K) and second highest (408 K) values by Sokolov and Minchenko; the literature, unfortunately, provides no other data (Ref. 2).</p> <p>For component 2, three phase transition temperatures are mentioned in Ref. 1, i.e., 621, 546, and 481 K, the second of which can be reasonably identified with the fusion temperature [T_{fus}(2)= 553.9+0.5 K] listed in Preface, Table 2. Consequently: (i) the transition temperature at 621 K (if actually existing) might correspond to some kind of transformation (undetected by DSC, see Preface, Table 2) within the liquid crystal field; and (ii) only the transition at 481 K should correspond to a solid state transformation, although the latter figure is almost 60 K higher than the single T_{trs}(2) value (424+3 K) listed in Table 2 of the Preface.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Minchenko, S.P. Zh. Obshch. Khim., 1977, 47, 740-742.</p> <p>(2) Sanesi, M.; Cingolani, A.; Tonelli, P.L.; Franzosini, P. AUXILIARY INFORMATION																																																																									
NOTES: <p>In the original paper the results were shown in graphical form. The above listed numerical values represent a private communication by one of the authors (F., P.) to the compiler.</p> <p>According to the authors, the trend of the liquidus branch richer in component 1 is close to ideal, and the formation of solid solutions in this region ought to be either insignificant, or at least contained within very narrow limits. Indeed, previous investigations by the same group (Ref. 2) stated that the cryometric constant of potassium methanoate was $K = 11.5 \pm 0.1 \text{ K molality}^{-1}$, and that $\lim_{m \rightarrow 0} (\Delta T/m) = 11.6 \text{ K molality}^{-1}$ (ΔT: experimental freezing point depression; m: molality of the solute) when KCl was the solute.</p>	METHOD/APPARATUS/PROCEDURE: <p>A Pyrex device, suitable for work under an inert atmosphere, and allowing one to observe the system visually, was employed (for details, see Ref. 1). The initial crystallization temperatures were measured with a Chromel-Alumel thermocouple checked by comparison with a certified Pt resistance thermometer, and connected with a L&N Type K-3 potentiometer.</p> <p>The system could not be investigated above 300 °C due to the thermal instability of the methanoate.</p>																																																																								
SOURCE AND PURITY OF MATERIALS: C. Erba RP materials, dried by heating under vacuum.	ESTIMATED ERROR: Temperature: accuracy probably $\pm 0.1 \text{ K}$ (compiler). REFERENCES: (1) Braghetti, M.; Leonesi, D.; Franzosini, P.; <i>Ric. Sci.</i> <u>1968</u> , 38, 116-118. (2) Leonesi, D.; Piantoni, G.; Berchiesi, G.; Franzosini, P. <i>Ric. Sci.</i> <u>1968</u> , 38, 702-705.																																																																								

<p>COMPONENTS:</p> <p>(1) Potassium methanoate (potassium formate); KCHO₂; [590-29-4]</p> <p>(2) Potassium thiocyanate; KCNS; [333-20-0]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p>	
<p>The liquidus of this binary was studied with visual methods by Sokolov and Pochtakova (Ref. 1), and by Berchiesi and Laffitte [Ref. 2, where reference is made to a previous investigation by Braghetti et al. (Ref. 3) for what concerns the branch richer in component 2, and the T_{trs} and $\Delta_{trs}H_m$ values of either components]. According to both papers, a single eutectic exists whose coordinates should be either 356 K and $100x_2 = 47.5$ (Ref. 1), or 351.7 K and $100x_2 = 46$ (Ref. 2).</p>	
<p>Substantially agreeing figures are reported for $T_{fus}(1)$ [440 K (Ref. 1); 441.85 K (Ref. 2)], $T_{fus}(2)$ [450 K (Ref. 1); 449.15 K (Ref. 2)], and $T_{trs}(2)$ [415.7 K (Ref. 4, quoted in Ref. 1); 415 K (Ref. 3, quoted in Ref. 2)]. Conversely, disagreement exists about the number and location of the solid state transitions of component 1, which ought to be three (at 430, 408, and 333 K, respectively) according to Ref. 5, quoted in Ref. 1, and only one (at 418 K) according to Ref. 3, quoted in Ref. 2. The latter information, however, ought to be looked at as more trustworthy being based on DSC records.</p>	
<p>According once more to Ref. 3, solid solutions ought to be absent (or at least contained within very narrow limits) in the composition range between pure component 2 and the eutectic, as suggested by the DSC traces. The authors could thus employ the well known equation</p>	
$T(2) = \frac{[\Delta_{fus}(2)H_m/R + \Delta_{trs}(2)H_m/R] + (A/R)(x_1)^2}{[\Delta_{fus}(2)S_m/R + \Delta_{trs}(2)S_m/R] - \ln x_2}$	
<p>to calculate the solid-liquid equilibrium temperatures, $T(2)/K$, relevant to the liquidus branch richer in component 2 (see curve a of Fig. 1), assuming the following numerical values: $\Delta_{fus}(2)H_m/R = 1545$ K; $\Delta_{trs}(2)H_m/R = 186$ K (to be introduced only when $T(2) \leq T_{trs}$); and $A/K = -800/R + (360/R)x_1$ (A/K: empirical factor introduced to take into account the non-ideal behavior of the mixtures; ideality represented by curve b).</p>	
<p>In the figure, the filled and empty circles correspond to data from Ref. 1 and Ref. 2, respectively. It is apparent that spreading is larger in the first set than in the second one, which, moreover, gives [at $T_{trs}(2)/K = 415$] a better evidence of the expected change of slope. Accordingly, and taking also into account the poor reliability of the $T_{trs}(1)$ values quoted in Ref. 1, the evaluator recommends Berchiesi and Laffitte's presentation (Ref. 2), although regretting that information was not extended to the solidus.</p>

AUXILIARY INFORMATION																																																																																											
METHOD/APPARATUS/PROCEDURE: The liquidus was determined with a visual method, (details in Ref. 2), supplemented with DSC measurements. The enthalpy changes (not to be listed here) associated with various thermodynamic processes were measured with differential flux calorimetry (using a modified Tian-Calvet calorimeter).	SOURCE AND PURITY OF MATERIALS: Not stated. Component 1 undergoes a phase transition at $T_{\text{trs}}(1)/\text{K} = 418$ (Ref. 1). Component 2 undergoes a phase transition at $T_{\text{trs}}(2)/\text{K} = 415$ (Ref. 1).

AUXILIARY INFORMATION																																																																									
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis.	SOURCE AND PURITY OF MATERIALS: Component 1: commercial "chemically pure" material recrystallized from methanoic acid; it undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 60, 135, 157$ (Ref. 1). Component 2: material prepared by reducing potassium nitrate with lead, melting at $t_{\text{fus}}(2)/^\circ\text{C} = 436$ after three recrystallizations; it undergoes a phase transition at $t_{\text{trs}}(2)/^\circ\text{C} = 45$ (Ref. 2).																																																																								
NOTE: Solid state transitions of component 1 should be three (occurring at 430, 408, and 333 K, respectively) according to Ref. 1, and only one (at 418 ± 1 K) according to Table 1 of the Preface. Unfortunately, no information from other sources is available. It can be noted, however, that, e.g., the trend of the liquidus branch richer in KCHO_2 of the binary $\text{K}/\text{CHO}_2, \text{NO}_2$ studied by Berchiesi et al. (Ref. 3) supports Table 1 statement. Moreover, the existence (and composition) of the intermediate compound ought to be more convincingly proved.	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).

COMPONENTS:

- (1) Potassium methanoate (potassium formate)
KCHO₂; [590-29-4]
(2) Potassium nitrate;
KNO₃; [7757-79-1]

EVALUATOR:

Franzosini, P.,
Dipartimento di Chimica Fisica,
Universita' di Pavia (ITALY).

CRITICAL EVALUATION:

This system was studied first (Ref. 1) by Dmitrevskaya who, on the basis of her visual polythermal investigation, claimed the existence of the congruently melting intermediate compound K₃(CHO₂)₂NO₃, able to give eutectics with either component, at 423 K and 100x₂= 32.5, and 419 K and 100x₂= 44, respectively.

Berchiesi et al. (Ref. 2) re-investigated the binary (employing again a visual method) as a side of the ternary K/CHO₂, CNS, NO₃, and found an incongruently melting intermediate compound [whose composition, argued from auxiliary DSC measurements, should be K₅(CHO₂)₄NO₃], a peritectic at 399.7 K and 100x₂= 26.2, and a eutectic at 387 K and 100x₂= 37.9.

The following considerations can help to evaluate the trustworthiness of these far different results.

Leonesi et al. (Ref. 3) performed cryometric measurements in molten KCHO₂, stating that the cryometric constant was $K_1 = 11.5 \pm 0.1$ K molality⁻¹ which corresponds to $\Delta_{\text{fus}}(1)H_m = 11.9$ kJ mol⁻¹ (2.84+0.03 kcal mol⁻¹ in the original text). The latter value is, in turn, in satisfactory agreement with those subsequently determined with DSC by Braghetti et al. (11.8 kJ mol⁻¹; Ref. 4), and with Calvet microcalorimetry by Berchiesi and Laffitte (11.5+0.1 kJ mol⁻¹; Ref. 5).

In particular, Leonesi et al. (Ref. 3) found limiting values

$$[\lim_{m_2 \rightarrow 0} (\Delta T/m_2)]/\nu = 11.5, 11.55, \text{ and } 11.4 \text{ K molality}^{-1}$$

for KNO₃ ($\nu = 1$; ν : number of cryometrically active foreign species), LiNO₃ ($\nu = 2$), and CsNO₃ ($\nu = 2$), respectively, which implies that a solubility of these solutes in KCHO₂ in the solid state should be either absent, or negligible. The three sets of ($\Delta T/\nu$) vs. x₁ data from Ref. 3 (KNO₃: empty circles; LiNO₃: empty squares; CsNO₃: filled squares), which exhibit a satisfactory mutual consistency, are compared in the figure with the data taken in K/CHO₂, NO₃ mixtures rich in component 1 by Berchiesi et al. (filled circles; Ref. 2), and by Dmitrevskaya (crosses; Ref. 1), respectively: it is apparent that the results from Ref. 1 are inconsistent with those from both Ref. 2 and Ref. 3.

Concerning solid state transformations of component 1, three transitions are quoted in Ref. 1 from Ref. 6 as occurring at 333, 408, and 430 K, respectively, whereas a single transition (at 418±1 K) is listed in Table 1 of the Preface. Berchiesi et al. (Ref. 2) make no explicit reference to any transition, but an inspection of their liquidus richest in component 1 allows one to observe a single change of slope around 418 K, i.e., in correspondence with the value from Table 1.

In conclusion, in the evaluator's opinion the data by Berchiesi et al. (Ref. 2) are to be recommended, although a better knowledge of the solidus would be desirable.

AUXILIARY INFORMATION																																																																									
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis.	SOURCE AND PURITY OF MATERIALS: Component 1: "chemically pure" material. Component 2: prepared from commercial propanoic acid (distilled before use) and "chemically pure" potassium carbonate; the recovered solid was recrystallized from n-butanol; it undergoes a phase transition at $t_{\text{trs}}(2)/^{\circ}\text{C} = 330$ (Ref. 1).																																																																								
NOTE: The occurrence of a continuous series of solid solutions in this binary seems likely. The fusion temperatures of both components [$T_{\text{fus}}(1) = 574$ K, and $T_{\text{fus}}(2) = 638$ K] are in reasonable agreement with the corresponding data listed in Preface, Table 1 (578.7±0.5 K, and 638.3±0.5 K, respectively). Conversely, there is no correspondence between the solid state transition temperature of component 2 quoted from Ref. 1 (603 K) and that of Table 1 (352.5±0.5 K). It is, however, to be noted that in other papers by the same group (see, e.g., Ref. 2) a transition of component 2 - ignored here - is quoted from the same Ref. 1 as occurring at 341 K.	ESTIMATED ERROR: Temperature: accuracy probably ±2 K (compiler).

CRITICAL EVALUATION:

The visual polythermal analysis was employed by Sokolov and Pochtakova (Ref. 1) to study the lower boundary of the isotropic liquid field. According to these authors, an intermediate compound of presumable composition $K_7C_2H_3O_2(C_4H_7O_2)_6$ ought to form, and two invariants, i.e., a eutectic, E [at 546 K (273 °C), and $100x_1 = 85.5$], and a "perekhodnaya tochka", P [at 623 K (350 °C), and $100x_1 = 20.5$], ought to exist.

Component 2, however, forms liquid crystals, which causes the statements about the composition of the intermediate compound and the occurrence of the invariant P to become inconsistent, as explained below. Sokolov and Pochtakova's fusion temperature [677 K (404 °C)], and solid state transition at 618 K (345 °C; quoted from Ref. 2) should be identified with the clearing and fusion temperatures of component 2, respectively.

More recently, Prisyazhnyi et al. (Ref. 3) - to whom Ref. 1 seems to be unknown - carried out a derivatographical re-investigation of the system, which allowed them to draw the lower boundaries of both the isotropic liquid, and the liquid crystal field. Their clearing [$T_{cl}(2) = 676$ K (403 °C)] and fusion [$T_{fus}(1) = 575$ K (302 °C); $T_{fus}(2) = 623$ K (350 °C)] temperatures substantially agree with the corresponding values from Table 1 of the Preface (677.3±0.5; 578.7±0.5, and 626.1±0.7 K, respectively). Prisyazhnyi et al.'s, and Sokolov and Pochtakova's results (filled and empty circles, respectively) are compared in the figure (IL: isotropic liquid; LC: liquid crystals), an inspection of which allows one to remark that: (i) the correct composition of the intermediate compound ought to be $K_5(C_2H_3O_2)_2(C_4H_7O_2)_3$ (Ref. 3) and not $K_7C_2H_3O_2(C_4H_7O_2)_6$ (Ref. 1); (ii) point P mentioned in Ref. 1 cannot be an invariant, but corresponds merely to an inflection (on the origin of which, however, no sure explanation can be offered by the evaluator) of the pertinent curve; and (iii) besides the eutectic, E, two more invariants exist, i.e., an M_E point, and an M' point. The abscissa of the latter being known only approximately, it can be hardly decided if this M' point is actually of the M'_E or of the M'_P type: in the former case, the complete phase diagram should be similar to Scheme D.1 of the Preface; in the latter case, to Scheme D.3.

The two-phase region pertinent to the liquid crystal - isotropic liquid equilibria might be so narrow as to have prevented Prisyazhnyi et al. to observe two distinct sets of points in this region, whereas the lack of information about eutectic fusion in the different samples submitted to derivatographical analysis remains rather surprising.

Finally, the following two points require attention.

(i) In Ref. 1 solid state transitions of component 1 are quoted from Ref. 2 as occurring at 428 and 331 K (155 and 58 °C, respectively), whereas mention is made in Preface (Table 1) of a single transition at 422.2±0.5 K.

(ii) Again in Ref. 1 (and from the same source), two more transformation temperatures, i.e., 558 and 463 K, respectively, are quoted for component 2 which lie each halfway between the two pairs of solid state transition temperatures (i.e., 562.2±0.6 and 540.8±1.1 K, and 467.2±0.5 and 461.4±1.0 K, respectively) also reported in Table 1 of the Preface.

AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: <p>The heating and cooling traces were recorded in an atmosphere of purified argon with an OD-102 derivatograph (MOM, Hungary) working at a rate of 6-8 K min⁻¹, and using Al₂O₃ as the reference material. Temperatures were measured with a Pt/Pt-Rh thermocouple. A hot-stage Amplival polarizing microscope was employed to detect the transformation points from the liquid crystalline into the isotropic liquid phase.</p>	SOURCE AND PURITY OF MATERIALS: Not stated. Component 1: $t_{fus}(1)/^{\circ}C$ about 302 (compiler). Component 2: $t_{fus}(2)/^{\circ}C$ about 350; $t_{clr}(2)/^{\circ}C$ about 403 (compiler). ESTIMATED ERROR: Temperature: accuracy not evaluable (compiler). REFERENCES:

<p>COMPONENTS:</p> <p>(1) Potassium ethanoate (potassium acetate); $KC_2H_3O_2$; [127-08-2]</p> <p>(2) Potassium iso.butanoate (potassium iso.butyrate); $Ki.C_4H_7O_2$; [19455-20-0]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov and Pochtakova (Ref. 1) who claimed the existence of: (i) a eutectic, E_1, at 564 K (291 °C) and $100x_1 = 86.5$; (ii) a eutectic, E_2, at 567 K (294 °C) and $100x_1 = 32$; and (iii) an intermediate compound, $K_5(C_2H_3O_2)_3(i.C_4H_7O_2)_2$, congruently melting at 578 K (305 °C).</p> <p>Component 2, however, forms liquid crystals. Therefore the temperature of 633 K (360 °C) given in Ref. 1 should be identified with the clearing (and not the fusion) temperature of this component, and compared with the $T_{c1r}(2)$ value (625.6+0.8 K) reported in Preface, Table 2.</p> <p>For the same component, three more phase transition temperatures are quoted in Ref. 1 from Ref. 2, i.e., 621, 546, and 481 K, the second of which can be reasonably identified with the fusion temperature [$T_{fus}(2) = 553.9+0.5$ K] listed in Table 2 of the Preface. Consequently: (i) the transition temperature at 621 K (if actually existing) might correspond to some kind of transformation (undetected by DSC, see Table 2) within the liquid crystal field; and (ii) only the transition at 481 K should correspond to a solid state transformation, although the latter figure is almost 60 K higher than the single $T_{trs}(2)$ value (424+3 K) listed in Preface, Table 2.</p> <p>The fusion temperature of component 1, $T_{fus}(1) = 574$ K (301 °C; Ref. 1), and the transition temperature [428 K (155 °C; quoted in Ref. 1 from Ref. 2)] satisfactorily correspond with the values listed in Table 1 of the Preface (578.7+0.5 K, and 422.2+0.5 K, respectively), whereas the other solid-solid transition quoted by the authors from Ref. 2 as occurring at 331 K (58 °C) has no correspondence in Table 1.</p> <p>In conclusion, the phase diagram ought to be similar to that shown in Scheme D.1 of the Preface. Accordingly, the eutectic E_2 should actually be an M'_E point. The existence of the intermediate compound $K_5(C_2H_3O_2)_3(i.C_4H_7O_2)_2$ seems reasonably supported by the available data.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Pochtakova, E.I. Zh. <p>AUXILIARY INFORMATION</p>																																																																									
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: "chemically pure" material recrystallized. Component 2: prepared from commercial "pure" grade iso.butanoic acid, distilled before use, and potassium "chemically pure" hydrogen carbonate (Ref. 1); then recrystallized from n-butanol. Component 1 undergoes phase transitions at $t_{trs}(1)/^\circ C = 58, 155$ (Ref. 2). Component 2 undergoes phase transitions at $t_{trs}(2)/^\circ C = 208, 273, 348$ (Ref. 2).</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																																																								
<p>REFERENCES:</p> <p>(1) Sokolov, N.M. <i>Zh. Obshch. Khim.</i> 1954, 24, 1150-1156. (2) Sokolov, N.M. <i>Tezisy Dokl. X Nauch. Konf. S.M.I.</i> 1956. (this is Ref. 6 in the original paper, and not Ref. 5 as erroneously quoted in the text; compiler).</p>																																																																									

<p>COMPONENTS:</p> <p>(1) Potassium ethanoate (potassium acetate); $KC_2H_3O_2$; [127-08-2]</p> <p>(2) Potassium pentanoate (potassium valerate); $KC_5H_9O_2$; [19455-21-1]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Pochtakova (Ref. 1) who claimed the existence of: (i) a eutectic point at 553 K (280 °C) and $100x_2 = 12.5$; (ii) a "perekhodnaya tochka" (likely a peritectic) at 607 K (334 °C) and $100x_2 = 52.5$; and (iii) an incongruently melting intermediate compound, $K_5(C_2H_3O_2)_2(C_5H_9O_2)_3$.</p> <p>Component 2, however, forms liquid crystals. Therefore, Pochtakova's fusion temperature, $T_{fus}(2) = 717$ K (444 °C), should be identified with the clearing temperature, the corresponding value from Table 1 of the Preface being 716 ± 2 K. The phase transition quoted by the author from Ref. 2 as occurring in the same component at 580 K (307 °C; Ref. 2) can be reasonably identified with the actual fusion temperature, the value from Preface, Table 1 being $T_{fus}(2) = 586.6 \pm 0.7$ K. No mention is made of further transformations, although Table 1 reports a solid state transition at 399.5 ± 0.9 K.</p> <p>Among the phase transition temperatures mentioned by Pochtakova for component 1, the fusion at 575 K (302 °C; Ref. 1), and the solid state transition at 428 K (155 °C; quoted from Ref. 2), can be satisfactorily identified with the corresponding values of Table 1 of the Preface, viz., 578.7 ± 0.5 K and 422.2 ± 0.5 K, respectively. On the contrary, the lower solid-solid transition quoted from Ref. 2 as occurring at 331 K (58 °C) has no correspondence in Table 1.</p> <p>In conclusion, it can be asserted that in Pochtakova's phase diagram the branch whose ends are $T_{clr}(2)$ and point P is relevant to isotropic liquid - liquid crystal equilibria, whereas it is hard to decide, on the basis of the available data, whether or not an intermediate compound is formed.</p> <p>The existence of the intermediate compound might be argued from analogy with the topology of the binary potassium ethanoate - potassium iso.butanoate (Ref. 3) where evidence was obtained for the formation of a 3:2 compound. Accordingly, the phase diagram might be similar to Scheme D.3 of the Preface with an M_p point at about 588 K (315 °C) and $100x_2$ about 40. In this case, Pochtakova's P point should be a mere inflection in the relevant branch.</p> <p>Conversely, if the existence of the compound is not accepted, the phase diagram might be interpreted with reference to Scheme B.2.</p> <p>REFERENCES:</p> <p>(1) Pochtakova, E.I. Zh. Obshch. Khim. 1966, 36, 3-8.</p> <p>(2) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956.</p> <p>(3) Sokolov, N.M.; Pochtakova, E.I. Zh. Obshch. Khim. 1960, 30, 1405-1410 (*); Russ. J. Gen. AUXILIARY INFORMATION																																																																															
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis.	SOURCE AND PURITY OF MATERIALS: Component 1: "chemically pure" material. Component 2: prepared from n-pentanoic acid and hydrogen carbonate (Ref. 1, where, however, carbonate instead of hydrogen carbonate was employed). Component 1 undergoes phase transitions at $t_{trs}(1)/^\circ C = 58, 155$ (Ref. 2). Component 2 undergoes a phase transition at $t_{trs}(2)/^\circ C = 307$ (Ref. 2).																																																																														
ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																																																															
REFERENCES: (1) Sokolov, N.M. Zh. Obshch. Khim. <u>1954</u> , 24, 1581-1593. (2) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. <u>1956</u> .																																																																															

<p>COMPONENTS:</p> <p>(1) Potassium ethanoate (potassium acetate); $KC_2H_3O_2$; [127-08-2]</p> <p>(2) Potassium iso.pentanoate (potassium iso.valerate); $Ki-C_5H_9O_2$; [589-46-8]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Pochtakova (Ref. 1), who claimed the existence of: (i) a eutectic, E, at 542 K (269 °C) and $100x_2 = 50$; (ii) a peritectic, P, at 543 K (270 °C) and $100x_2 = 18.5$; and (iii) an incongruently melting compound, of probable composition $K_8(C_2H_3O_2)_7i.C_5H_9O_2$.</p> <p>Component 2, however, forms liquid crystals. Therefore the fusion temperature, $T_{fus}(2) = 669$ K (396 °C) reported by the author should be identified with the clearing temperature, the corresponding value from Preface, Table 2 being 679 ± 2 K. No mention is made by the author of the actual fusion which occurs at 531 ± 3 K according to Table 2: the latter figure is supported by the trend of the thermomagnetical curves plotted by Duruz and Ubbelohde (Ref. 2).</p> <p>As for the other phase transitions quoted by Pochtakova from Ref. 3 at 327 and 618 K (54 and 345 °C, respectively), no identification is possible with the findings by other investigators, inasmuch as: (i) no transformation is reported in Table 2 as occurring below $T_{fus}(2) = 531 \pm 3$ K; and (ii) no transformation is reported in Table 2 or in Ref. 2 as occurring within the field of existence of the mesomorphic liquid. It is a bit puzzling the fact that for potassium iso.pentanoate Dmitrevskaya and Sokolov (Ref. 4) quote from Ref. 3 (unavailable to the evaluator) transitions at 618, 493, and 473 K (ignoring that quoted by Pochtakova at 327 K), and Pochtakova quotes from the same source transitions at 618 and 327 K (ignoring those quoted by Dmitrevskaya and Sokolov at 493 and 473 K).</p> <p>Component 1, as quoted in Ref. 1 from Ref. 3, undergoes phase transitions at 331 and 428 K (58 and 155 °C, respectively), the latter figure being in reasonable agreement with the T_{trs} value (422.2 ± 0.5 K) from Table 1 of the Preface.</p> <p>The available data do not seem sufficient to prove unambiguously the existence of any intermediate compound. Should it exist, the phase relations at $50 < 100x_2 < 100$ could be reasonably interpreted with reference to Scheme D.1: Pochtakova's eutectic could be actually an M_E^* point, and a further invariant of the M_E type should exist.</p> <p>REFERENCES:</p> <p>(1) Pochtakova, E.I. Zh. Obshch. Khim. <u>1963</u>, 33, 342-347.</p> <p>(2) Duruz, J.J.; Ubbelohde, A.R. Proc. Roy. Soc. London <u>1975</u>, A 342, 39-49.</p> <p>(3) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. <p>VARIABLES:</p> <p>Temperature.</p>	<p>PREPARED BY:</p> <p>Baldini, P.</p>
<p>EXPERIMENTAL VALUES:</p> <p>The results are given only in graphical form (see figure). The system was investigated at $0 \leq 100x_2 \leq 8$.</p> <p>Characteristic point(s): Eutectic, E, at 293.6 °C and $100x_1 = 93.3$ (authors).</p> <div data-bbox="709 713 1193 1201" style="text-align: center;"> </div>	
<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>A Pyrex device, suitable for work under an inert atmosphere, and allowing one to observe the system visually, was employed (for details, see Ref. 1). The initial crystallization temperatures were measured with a Chromel-Alumel thermocouple checked with a comparison with a certified Pt resistance thermometer, and connected with a L&N Type K-3 potentiometer.</p>	<p>molality⁻¹, respectively] previously found by Braghetti et al. (Ref. 1) when the same halides were employed as solutes in molten potassium ethanoate (the cryometric constant of which is: $K_1 = 18.0 \pm 0.3$ K molality⁻¹; Ref. 1).</p> <p>SOURCE AND PURITY OF MATERIALS:</p> <p>C. Erba RP materials, dried by heating under vacuum (private communication by the authors to the compiler).</p>
<p>NOTE:</p> <p>Higher precision, and satisfactory mutual consistency of the results obtained by Piantoni et al. for the three binaries $\text{K}/\text{C}_2\text{H}_3\text{O}_2$, (Br, Cl, I) suggest to prefer here the data by these authors to those by Il'yasov and Bergman (Ref. 2). Increasingly positive deviation from ideality was observed by Piantoni et al. for the liquidus branch richer in the halide when KCl, KBr, and KI were successively taken into account. This is consistent with the (cryometric) limiting values $[\lim (\Delta T/m_2) = 17.7, 17.4, \text{ and } 16.0 \text{ K } m_2 \rightarrow 0$</p>	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 0.1 K.</p>
	<p>REFERENCES:</p> <p>(1) Braghetti, M.; Leonesi, D.; Franzosini, P. <i>Ric. Sci.</i> 1968, <i>38</i>, 116-118. (2) Il'yasov, I.I.; Bergman, A.G. <i>Zh. Obshch. Khim.</i> 1960, <i>30</i>, 355-358.</p>

COMPONENTS: (1) Potassium ethanoate (potassium acetate); $\text{KC}_2\text{H}_3\text{O}_2$; [127-08-2] (2) Potassium thiocyanate; KCNS ; [333-20-0]	EVALUATOR Spinolo, G., Dipartimento di Chimica Fisica, Università di Pavia (ITALY).																								
CRITICAL EVALUATION: <p>The binary $\text{K}/\text{C}_2\text{H}_3\text{O}_2$, CNS was studied by Golubeva et al. (Ref. 1), and by Sokolov (Ref. 2). In both papers, the visual polythermal analysis was employed to draw the lower boundary of the isotropic liquid field.</p> <p>Concerning the thermal behavior of component 1, it can be noted that a reasonable agreement exists: (i) between the fusion temperatures from Refs. 1, 2, and that listed in Table 1 of the Preface (578.7 ± 0.5 K); and (ii) between Sokolov's (Ref. 2) higher transition temperature (428 K), and the single $T_{\text{trs}}(1)$ value (422.2 ± 0.5 K) from Table 1. No correspondence with Table 1 can be found for Sokolov's lower transition (331 K). No solid state transformation of this component is mentioned in Ref. 1.</p> <p>The main features of the phase diagram given in either source exhibit rather close similarities, as shown here:</p>																									
<table border="1"> <thead> <tr> <th></th> <th>Ref. 1</th> <th>Ref. 2</th> </tr> </thead> <tbody> <tr> <td>$T_{\text{fus}}(1)/\text{K}$:</td> <td>579</td> <td>575</td> </tr> <tr> <td>$T_{\text{fus}}(2)/\text{K}$:</td> <td>449</td> <td>450</td> </tr> <tr> <td>Intermediate compound</td> <td>$\text{K}_3\text{C}_2\text{H}_3\text{O}_2(\text{CNS})_2$</td> <td>$\text{K}_3\text{C}_2\text{H}_3\text{O}_2(\text{CNS})_2$</td> </tr> <tr> <td>Eutectic E_1; T/K:</td> <td>405</td> <td>410-412</td> </tr> <tr> <td>Eutectic E_1; $100x_1$:</td> <td>42.5</td> <td>39</td> </tr> <tr> <td>Eutectic E_2; T/K:</td> <td>403</td> <td>408</td> </tr> <tr> <td>Eutectic E_2; $100x_1$:</td> <td>27</td> <td>22.5</td> </tr> </tbody> </table>			Ref. 1	Ref. 2	$T_{\text{fus}}(1)/\text{K}$:	579	575	$T_{\text{fus}}(2)/\text{K}$:	449	450	Intermediate compound	$\text{K}_3\text{C}_2\text{H}_3\text{O}_2(\text{CNS})_2$	$\text{K}_3\text{C}_2\text{H}_3\text{O}_2(\text{CNS})_2$	Eutectic E_1 ; T/K:	405	410-412	Eutectic E_1 ; $100x_1$:	42.5	39	Eutectic E_2 ; T/K:	403	408	Eutectic E_2 ; $100x_1$:	27	22.5

<p>COMPONENTS:</p> <p>(1) Potassium ethanoate (potassium acetate); $KC_2H_3O_2$; [127-08-2]</p> <p>(2) Potassium nitrite; KNO_2; [7758-09-0]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied by Bergman and Evdokimova (Ref. 1), and by Sokolov and Minich (Ref. 2): in both papers, the visual polythermal analysis was employed to draw the lower boundary of the isotropic liquid field.</p> <p>Concerning the thermal behavior of component 1, it can be noted that a reasonable agreement exists: (i) between the fusion temperature (575 K) from Refs. 1, 2, and that listed in Table 1 of the Preface (578.7+0.5 K); and (ii) between Sokolov and Minich's (Ref. 2) higher transition temperature (428 K), and the single $T_{trs}(1)$ value (422.2+0.5 K) from Table 1. No correspondence with Table 1 can be found for Sokolov and Minich's lower transition (331 K). No solid state transformation of this component is mentioned in Ref. 1.</p> <p>The experimental points from both papers exhibit rather similar trends; a discrepancy, however, exists about interpretation of the results. Indeed, in Sokolov and Minich's opinion (Ref. 2), the system ought to be characterized by a eutectic and a peritectic, and accordingly by the presence of an incongruently melting intermediate compound. Conversely, in Bergman and Evdokimova's opinion (Ref. 1), the system shows a single invariant, i.e., a eutectic at 573 K and $100x_2 = 50$. It is worth mentioning that, in the evaluator's opinion, the existence of a third (intermediate) branch of the liquidus - if any - might be supported rather by the experimental data from Ref. 1 than by those from Ref. 2. Moreover, the composition of the intermediate compound suggested in Ref. 2 is not compatible with Sokolov and Minich's experimental values.</p> <p>In conclusion, the evaluator is inclined to think that the actual existence of an intermediate compound is poorly supported by the available data, and therefore to prefer the picture of the system drawn in Ref. 1.</p> <p>REFERENCES:</p> <p>(1) Bergman, A.G.; Evdokimova, K.A. AUXILIARY INFORMATION																																																																									
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis.	SOURCE AND PURITY OF MATERIALS: Component 1: commercial "chemically pure" material recrystallized from water; it undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 58, 155$ (Ref. 1). Component 2: material prepared by reducing potassium nitrate with lead, melting at $t_{\text{fus}}(2)/^\circ\text{C} = 436$ after three recrystallizations; it undergoes a phase transition at $t_{\text{trs}}(2)/^\circ\text{C} = 45$ (Ref. 2). ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler). REFERENCES: (1) Sokolov, N.M. <i>Tezisy Dokl. X Nauch. Konf. S.M.I.</i> 1956. (2) Berul', S.I.; Bergman, A.G. <i>Izv. Sektora Fiz.-Khim. Anal.</i> 1952, 21, 178-183.																																																																								

COMPONENTS: (1) Potassium ethanoate (potassium acetate); $\text{KC}_2\text{H}_3\text{O}_2$; [127-08-2] (2) Potassium nitrate; KNO_3 ; [7757-79-1]	EVALUATOR: Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).
--	---

CRITICAL EVALUATION:

This binary was studied by Bergman and Evdokimova (Ref. 1), Diogenov et al. (Ref. 2), Gimel'shtein (Ref. 3), and Diogenov and Chumakova (Ref. 4). In Ref. 3, the automatic record of the heating curves with a DTA device allowed the author to gain a complete picture of the phase diagram in the superambient region, whereas in Refs. 1, 2, and 4 the visual polythermal analysis was employed to draw merely the lower boundary of the isotropic liquid field.

Concerning component 1, the fusion temperatures from Refs. 1-4 (575, 583, 586, and 575 K, respectively) fluctuate (rather widely) around the $T_{\text{fus}}(1)$ value (578.7±0.5 K) listed in Preface, Table 1. Moreover, a reasonable agreement exists between the (single) solid state transition temperature reported in Ref. 3 and Table 1 (428 K and 422.2±0.5 K, respectively), whereas, in the evaluator's opinion, poor reliability is to be attached to Diogenov et al.'s (Ref. 2) assertion that a transition occurs at 565 K, because no support to it is provided by the findings of any author foreign to Diogenov's group (Ref. 5).

The main features of the phase diagram reported in Refs. 1-4 appear to be rather similar, so that the following points can be taken as unambiguously stated: (i) a 1:1 intermediate compound is formed; (ii) it melts congruently, and, accordingly, two eutectics separate its crystallization branches from those relevant to the pure components; and (iii) a fair agreement exists among the coordinates of the invariants provided by Refs. 1, 3, and 4 (see below), whereas the temperature values from Ref. 2 appear to be systematically too low.

 Eutectic, E₂, at 222 °C and 100x₂= 61.5 (authors).

Intermediate compound(s):
 K₂C₂H₃O₂NO₃, congruently melting at 238 °C (authors).

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

Visual polythermal analysis: the temperatures of initial crystallization were measured with a Nichrome-Constantane thermocouple and a 17 mV full-scale millivoltmeter.

ESTIMATED ERROR:

Temperature: accuracy probably ± 2 K (compiler).

SOURCE AND PURITY OF MATERIALS:

Source not stated. Component 2: in the temperature field of interest it undergoes a phase transition at $t_{\text{trs}}(2)/^{\circ}\text{C} = 316-318$ (Ref. 1).

<p>AUXILIARY INFORMATION</p>																																																																									
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis. Temperature of initial crystallization measured with a Nichrome-Constantane thermocouple checked at the boiling point of water, and at the fusion points of benzoic acid, mannitol, succinic acid, silver nitrate, tin, potassium nitrate, and potassium dichromate. Mixtures melted in a glass tube inserted into a wider tube to ensure uniform heating. Glass fiber stirrer used.</p> <p>NOTE:</p> <p>A substantial agreement exists between the solid state transition and fusion temperatures reported by Dmitrevskaya and Sokolov (341 and 638 K, respectively) for component 1, and those listed in Preface, Table 1 (352.5 ± 0.5 and 638.3 ± 0.5 K, respectively).</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1 prepared by adding a small excess of distilled commercial propanoic acid to a solution of the "chemically pure" hydrogen carbonate; the solid recovered after evaporation of the solvent was recrystallized from n-butanol. Component 2: "chemically pure" material recrystallized. Component 1 undergoes a phase transition at $t_{trs}(1)/^\circ C = 68$ (Ref. 1). Component 2 undergoes phase transitions at $t_{trs}(2)/^\circ C = 124, 316$ (current literature).</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956.</p>																																																																								

<p>COMPONENTS:</p> <p>(1) Potassium butanoate (potassium butyrate); $KC_4H_7O_2$; [589-39-9]</p> <p>(2) Potassium thiocyanate; $KCNS$; [333-20-0]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov and Pochtakova (Ref. 1), who suggested the existence of: (i) an intermediate compound of probable composition $K_7(C_4H_7O_2)_6CNS$; (ii) a "perekhodnaya tochka" (likely a peritectic), P, at 608 K (335 °C) and $100x_1 = 82$; and (iii) a eutectic, E, at 443 K (170 °C) and $100x_1 = 6.5$.</p> <p>Component 1, however, forms liquid crystals. Therefore, the fusion temperature, $T_{fus}(1) = 677$ K (404 °C), reported in Ref. 1 should be identified with the clearing temperature, the corresponding value from Table 1 of the Preface being $T_{clr}(1) = 677.3 \pm 0.5$ K.</p> <p>For the same component, the phase transition temperatures quoted (from Ref. 2) in Ref. 1, viz., 618 K (345 °C), 553-558 K (280-285 °C), and 463 K (190 °C), might correspond respectively to the fusion temperature (626.1 ± 0.7 K) and to the first and third solid state transition temperatures (562.2 ± 0.6 K, and 467.2 ± 0.5 K) of Table 1 of the Preface. No mention is made by the authors of other phase transitions, although in Table 1 two more T_{trs} values are reported (540.8 ± 1.1 K and 461.4 ± 1.0 K).</p> <p>The phase diagram as suggested by the authors can be considered as adequate only for the region (rich in component 2) including the eutectic, whereas it does not seem reliable in the remaining part.</p> <p>In particular:</p> <p>(1) the "perekhodnaya tochka", P, should rather be an M_p point, at which the equilibria involving the isotropic liquid and the liquid crystals might be those described in Preface, Scheme B.1;</p> <p>(ii) the available data cannot be considered as sufficient to support the existence of any intermediate compound.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Pochtakova, E.I. Zh. Obshch. Khim. 1958, 28, 1693-1700 (*); Russ. J. Gen. Chem. (Engl. Transl.) 1958, 28, 1741-1747.</p> <p>(2) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956.</p>

AUXILIARY INFORMATION																																																																															
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis. Temperatures measured with a Nichrome- Constantane thermocouple.	SOURCE AND PURITY OF MATERIALS: Component 1: synthesized from "chemically pure" potassium hydrogen carbonate and n- butanoic acid (Ref. 1, where, however, carbonates instead of hydrogen carbonates are employed; compiler), and recrystallized from n-butanol; it undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 190, 280-285,$ 345 (Ref. 2). Component 2: commercial material recrystallized once from water and once from alcohol.																																																																														
	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																																																														
	REFERENCES: (1) Sokolov, N.M. <i>Zh. Obshch. Khim.</i> 1954, 24, 1581-1593. (2) Sokolov, N.M. <i>Tezisy Dokl. X Nauch. Konf. S.M.I.</i> 1956.																																																																														

<p>COMPONENTS:</p> <p>(1) Potassium butanoate (potassium butyrate); $KC_4H_7O_2$; [589-39-9]</p> <p>(2) Potassium nitrite; KNO_2; [7758-09-0]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>The visual polythermal analysis was employed by Sokolov and Minich (Ref. 1) to study the lower boundary of the isotropic liquid field: they claimed the occurrence of a congruently melting intermediate compound [of tentative composition $K_8(C_4H_7O_2)_5(NO_2)_3$], able to give eutectics with either component.</p> <p>Component 1, however, forms liquid crystals. Therefore, the phase diagram has to be re-interpreted, possibly with reference to Preface, Scheme D.1. In this case, Sokolov and Minich's eutectic E_1 should be an M'_E point, and a further (still undetected) invariant type M_E ought to exist.</p> <p>The fusion temperature, $T_{fus}(1) = 677$ K, reported in Ref. 1, should be identified with the clearing temperature of component 1, and agrees fairly with the $T_{clr}(1)$ value (677.3 ± 0.5 K) listed in Preface, Table 1.</p> <p>Neither of the phase transformation temperatures, i.e., 553-558 and 463 K, quoted in Ref. 1 from Ref. 2 for the same component correspond to the $T_{fus}(1)$ value (626.1 ± 0.7 K) given in Table 1, inasmuch as they lie each halfway between the two pairs of solid state transition temperatures (i.e., 562.2 ± 0.6 and 540.8 ± 1.1 K, and 467.2 ± 0.5 and 461.4 ± 1.0 K, respectively) also reported in Table 1. It is, however, to be noted that in other papers by the same group (see, e.g., Ref. 3) a phase transformation occurring at 618 K, i.e., close to the $T_{fus}(1)$ value of Table 1, is also mentioned.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Minich, M.A. Zh. <p>AUXILIARY INFORMATION</p>																																																																									
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: prepared from "chemically pure" KHCO_3 and the fatty acid, and recrystallized from n-butanol after having been deposited from the aqueous solution and dried; it undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 190, 280-285$ (Ref. 1). Component 2: material prepared by reducing potassium nitrate with lead, melting at $t_{\text{fus}}(2)/^\circ\text{C} = 436$ after three recrystallizations; it undergoes a phase transition at $t_{\text{trs}}(2)/^\circ\text{C} = 45$ (Ref. 2).</p>																																																																								
	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																																																								
	<p>REFERENCES:</p> <p>(1) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. <u>1956</u>. (2) Berul', S.I.; Bergman, A.G. Izv. Sektora Fiz.-Khim. Anal. <u>1952</u>, 21, 178-183.</p>																																																																								

<p>COMPONENTS:</p> <p>(1) Potassium butanoate (potassium butyrate); $KC_4H_7O_2$; [589-39-9]</p> <p>(2) Potassium nitrate; KNO_3; [7757-79-1]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Dmitrevskaya (Ref. 1), who, on the basis of her visual polythermal investigation, suggested the phase diagram to be of the eutectic type, the invariant point being at 556 K (283 °C) and $100x_2 = 58$.</p> <p>Component 1, however, forms liquid crystals. Therefore, Dmitrevskaya's fusion temperature, $T_{fus}(1) = 677$ K (404 °C), should be identified with the clearing temperature of potassium butanoate, the corresponding value from Preface, Table 1 being $T_{clr}(1) = 677.3 \pm 0.5$ K.</p> <p>Accordingly, it seems likely that the actual phase diagram of this system should correspond to Preface, Scheme B.1 or B.2.</p> <p>Among the phase transformation temperatures of component 1 quoted in Ref. 1 from Ref. 2 (i.e., 618, 553-558, and 463 K) the first one can be reasonably identified with the fusion temperature (626.1 ± 0.7 K) listed in Table 1, whereas the second and third ones lie each halfway between the two pairs of solid state transition temperatures (i.e., 562.2 ± 0.6 and 540.8 ± 1.1 K, and 467.2 ± 0.5 and 461.4 ± 1.0 K, respectively) also reported in Table 1.</p> <p>REFERENCES:</p> <p>(1) Dmitrevskaya, O.I. <p>AUXILIARY INFORMATION</p>																																																																									
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis. Temperatures measured with a Nichrome-Constantane thermocouple.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1 synthesized from "chemically pure" potassium hydrogen carbonate and n-butanoic acid twice distilled. "Chemically pure" component 2 recrystallized and dried to constant mass. Component 1 undergoes phase transitions at $t_{trs}(1)/^\circ C=190, 280-285, 345$ (Ref. 1). Component 2 undergoes phase transitions at $t_{trs}(2)/^\circ C=124, 316$ (current literature).</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																																																								
	<p>REFERENCES:</p> <p>(1) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956.</p>																																																																								

<p>COMPONENTS:</p> <p>(1) Potassium iso.butanoate (potassium iso.butyrate); $K_1.C_4H_7O_2$; [19455-20-0]</p> <p>(2) Potassium nitrite; KNO_2; [7758-09-0]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>The visual polythermal analysis was employed by Sokolov and Minich (Ref. 1) to study the lower boundary of the isotropic liquid field; they claimed the formation of a continuous series of solid solutions with a minimum at 535 K (262 °C) and $100x_2 = 32.5$.</p> <p>Component 1, however, goes through the liquid crystalline state before to turn into a clear melt. Accordingly, the topology of the system has to be re-interpreted, a possibility (not very convincing, however) being that shown in Preface, Scheme B.3 which is based on the assumption that continuous solutions do form between solid KNO_2 and solid $K_1.C_4H_7O_2$.</p> <p>Sokolov and Minich's fusion temperature of component 1, i.e., 638 K (365 °C), should be identified with the $T_{clr}(1)$ value (625.6+0.8 K) listed in Preface, Table 2. The discrepancy between the two figures is noticeable: in previous papers by Sokolov's group, however, lower values, i.e., 629 K (Ref. 2) and 633 K (Ref. 3), were reported.</p> <p>It is further to be noted that three phase transition temperatures are quoted in Ref. 1 from Ref. 4 for component 1, i.e., 621, 546, and 481 K, the second of which can be reasonably identified with the fusion temperature [$T_{fus}(1) = 553.9+0.5$ K] listed in Table 2 of the Preface. Consequently: (i) the transition temperature at 621 K (if actually existing) might correspond to some kind of transformation (undetected by DSC, see Table 2) within the liquid crystal field; and (ii) only the transition at 481 K should correspond to a solid state transformation, although the latter figure is almost 60 K higher than the single $T_{trs}(1)$ value (424+3 K) listed in Table 2.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Minich, M.A. Zh. AUXILIARY INFORMATION																																																																									
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis.	SOURCE AND PURITY OF MATERIALS: Component 1: prepared from "chemically pure" $KHCO_3$ and the fatty acid, and recrystallized from n-butanol after having been deposited from the aqueous solution and dried; it undergoes phase transitions at $t_{trs}(1)/^\circ C = 208, 273, 348$ (Ref. 1). Component 2: material prepared by reducing potassium nitrate with lead, melting at $t_{fus}(2)/^\circ C = 436$ after three recrystallizations; it undergoes a phase transition at $t_{trs}(2)/^\circ C = 45$ (Ref. 2). ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																																																								
	REFERENCES: (1) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956. (2) Berul', S.I.; Bergman, A.G. Izv. Sektora Fiz.-Khim. Anal. 1952, 21, 178-183.																																																																								

<p>COMPONENTS:</p> <p>(1) Potassium iso.butanoate (potassium iso.butyrate); $K_1.C_4H_7O_2$; [19455-20-0]</p> <p>(2) Potassium nitrate; KNO_3; [7757-79-1]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied only by Dmitrevskaya and Sokolov (Ref. 1). On the basis of their visual polythermal results, they claimed the existence of: (i) an incongruently melting intermediate compound of supposed composition $K_2i.C_4H_7O_2NO_3$; (ii) a "perekhodnaya tochka" (likely a peritectic), P, at 529 K (256 °C) and $100x_2 = 47.5$; and (iii) a eutectic at 526 K (253 °C) and $100x_2 = 32.5$.</p> <p>Component 1, however, goes through the liquid crystalline state before to turn into a clear melt. Therefore, the authors' fusion temperature [$T_{fus}(1) = 629$ K (356 °C)] should be identified with the clearing temperature, the corresponding value from Table 2 of the Preface being $T_{clr}(1) = 625.6 \pm 0.8$ K.</p> <p>Moreover, three phase transition temperatures are quoted in Ref. 1 from Ref. 2 for the same component, i.e., 621, 546, and 481 K, the second of which can be reasonably identified with the fusion temperature [$T_{fus}(1) = 553.9 \pm 0.5$ K] listed in Preface, Table 2. Consequently: (i) the transition temperature at 621 K (if actually existing) might correspond to some kind of transformation (undetected by DSC, see Table 2) within the liquid crystal field; and (ii) only the transition at 481 K should correspond to a solid state transformation, although the latter figure is almost 60 K higher than the single $T_{LRS}(1)$ value (424±3 K) listed in Table 2.</p> <p>In conclusion, the authors' interpretation of the topology of this system is to be modified. In the evaluator's opinion, it seems reasonable to assume that the phase diagram could be similar to that shown in Preface, Scheme D.1, allowance being made for the fact that in the present case the intermediate compound is incongruently (instead of congruently) melting. Dmitrevskaya and Sokolov's eutectic should actually be an M'_E point, and a further invariant, type M_E, ought to exist. At any rate, a re-investigation of the system would be desirable, in order to obtain information on the solidus, and to assess unambiguously the composition of the intermediate compound.</p> <p>REFERENCES:</p> <p>(1) Dmitrevskaya, O.I.; Sokolov, N.M. <p>COMPONENTS:</p> <p>(1) Potassium pentanoate (potassium valerate); $KC_5H_9O_2$; [19455-21-1]</p> <p>(2) Potassium nitrite; KNO_2; [7758-09-0]</p>	<p>EVALUATOR:</p> <p>Schiraldi, A., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>The visual polythermal analysis was employed by Sokolov and Minich (Ref. 1) to study the lower boundary of the isotropic liquid field: they claimed the occurrence of a congruently melting intermediate compound [of tentative composition $K_7(C_5H_9O_2)_4(NO_2)_3$], able to give eutectics with either component.</p> <p>Component 1, however, forms liquid crystals. Therefore, the phase diagram has to be re-interpreted, possibly with reference to Preface, Scheme D.1. In this case, Sokolov and Minich's eutectic E_1 should be an M'_E point, and a further (still undetected) invariant type M_E ought to exist.</p> <p>The fusion temperature, $T_{fus}(1) = 717$ K, reported in Ref. 1, should be identified with the clearing temperature of component 1, and agrees fairly with the $T_{clr}(1)$ value (716±2 K) listed in Preface, Table 1. Moreover, the transition temperature $T_{trs}(1) = 580$ K (307 °C) quoted in Ref. 1 from Ref. 2 should in turn be identified with the actual fusion temperature, the corresponding value from Table 1 of the Preface being 586.6 ± 0.7 K.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Minich, M.A. Zh. <p>AUXILIARY INFORMATION</p>																																																																									
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: prepared from n-pentanoic acid and the carbonate (Ref. 1); it undergoes a phase transition at $t_{trs}(1)/^\circ C = 307$ (Ref. 2). Component 2: "chemically pure" material recrystallized; it undergoes phase transitions at $t_{trs}(2)/^\circ C = 124, 316$ (current literature).</p>																																																																								
	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																																																								
	<p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. Khim. <u>1954</u>, 24, 1581-1593. (2) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. <u>1956</u>.</p>																																																																								

<p>COMPONENTS:</p> <p>(1) Potassium iso.pentanoate (potassium iso.valerate); $Ki.C_5H_9O_2$; [589-46-8]</p> <p>(2) Potassium nitrite; KNO_2; [7758-09-0]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>The visual polythermal analysis was employed by Sokolov and Minich (Ref. 1) to study the lower boundary of the isotropic liquid field: they claimed the formation of a continuous series of solid solutions with a minimum at 562 K (289 °C) and $100x_2 = 37.5$.</p> <p>Component 1, however, goes through the liquid crystalline state before to turn into a clear melt. Therefore, the fusion temperature, $T_{fus}(1) = 669$ K (396 °C), reported by the authors should be identified with the clearing temperature, the corresponding value from Table 2 in the Preface being $T_{cl}(1) = 679 \pm 2$ K. No mention is made by the authors of the actual fusion which occurs at 531 ± 3 K (Table 2): the latter figure is supported by the trend of the thermomagnetical curves plotted by Duruz and Ubbelohde (Ref. 2). Accordingly, the topology of the system has to be re-interpreted, a possibility (not very convincing, however) being that shown in Preface, Scheme B.3, which is based on the assumption that continuous solutions do form between solid KNO_2 and solid $Ki.C_5H_9O_2$.</p> <p>As for the other phase transitions quoted by the authors for the same component from Ref. 3, at 327, and 618 K (54, and 345 °C, respectively), no identification is possible with the findings by other investigators, inasmuch as: (i) no transformation is reported in Table 2 of the Preface as occurring below $T_{fus}(1) = 531 \pm 3$ K; and (ii) no transformation is reported either in Table 2 or in Ref. 2 as occurring within the field of existence of the mesomorphic liquid. It is, however, to be stressed that the transition temperatures mentioned by Sokolov and Minich do not seem to be trustworthy: indeed, it is a bit puzzling the fact that for potassium iso.pentanoate Dmitrevskaya and Sokolov (Ref. 4) quote from Ref. 3 transitions at 618, 493, and 473 K, ignoring that quoted by Sokolov and Minich at 327 K.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; Minich, M.A. Zh. <p>AUXILIARY INFORMATION</p>																																																																									
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: prepared from "chemically pure" $KHCO_3$ and the fatty acid, and recrystallized from n-butanol after having been deposited from the aqueous solution and dried; it undergoes phase transitions at $t_{trs}(1)/^{\circ}C= 54, 345$ (Ref. 1). Component 2: material prepared by reducing potassium nitrate with lead, melting at $t_{fus}(2)/^{\circ}C= 436$ after three recrystallizations; it undergoes a phase transition at $t_{trs}(2)/^{\circ}C= 45$ (Ref. 2).</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956. (2) Berul', S.I.; Bergman, A.G. Izv. Sektora Fiz.-Khim. Anal. 1952, 21, 178-183.</p>																																																																								

<p>COMPONENTS:</p> <p>(1) Potassium iso.pentanoate (potassium iso.valerate); $K_1.C_5H_9O_2$; [589-46-8]</p> <p>(2) Potassium nitrate; KNO_3; [7757-79-1]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Dmitrevskaya and Sokolov (Ref. 1), who claimed the existence of: (i) a eutectic, E_1, at 557 K (284 °C) and $100x_2 = 27.5$; (ii) a eutectic, E_2, at either 553 K (280 °C; according to visual polythermal determinations), or 549 K (276 °C; according to thermographical analysis), and $100x_2 = 46.0$; and (iii) an intermediate compound $K_3(i.C_5H_9O_2)_2NO_3$, congruently melting at 557 ± 2 K (284 \pm 2 °C).</p> <p>Component 1, however, forms liquid crystals. Therefore, the fusion temperature, $T_{fus}(1) = 669$ K (396 °C), reported by the authors should be identified with the clearing temperature, the corresponding value from Preface, Table 2 being $T_{clr}(1) = 679 \pm 2$ K. No mention is made by the authors of the actual fusion which occurs at 531 ± 3 K (Table 2): the latter figure is supported by the trend of the thermomagnetical curves plotted by Duruz and Ubbelohde (Ref. 2).</p> <p>As for the other phase transitions quoted by the authors for component 1 from Ref. 3, at 473, 493, and 618 K (200, 220, and 345 °C, respectively), no identification is possible with the findings by other investigators, inasmuch as: (i) no transformation is reported in Table 2 of the Preface as occurring below $T_{fus}(1) = 531 \pm 3$ K; and (ii) no transformation is reported either in Table 2 or in Ref. 2 as occurring within the field of existence of the mesomorphic liquid. It is, however, to be stressed that the transition temperatures mentioned by Dmitrevskaya and Sokolov do not seem to be trustworthy: indeed, it is a bit puzzling the fact that for potassium iso.pentanoate Dmitrevskaya and Sokolov (Ref. 1) quote from Ref. 3 transitions at 618, 493, and 473 K, whereas, e.g., Pochtakova (Ref. 4) quotes from the same source transitions at 618 and 327 K (ignoring those quoted by Dmitrevskaya and Sokolov at 493 and 473 K).</p> <p>The interpretation of the phase diagram should be modified in the region rich in component 1. The evaluator is inclined to think that: (i) the transition reported (for component 1) in Ref. 3 at 618 K is erratic; (ii) despite the absence of thermographical evidence for the occurrence of fusion at about 530 K, this part of the diagram ought to be similar to that shown in Preface, Scheme D.1, the eutectic E_1 actually being an M_E^* point. Accordingly, a further invariant of the M_E type should exist at lower temperature.</p> <p>The composition of the intermediate compound could coincide with that suggested by the authors, viz., $100x_2 = 33.3$, and the remaining part of the diagram seems reliable.</p> <p>REFERENCES:</p> <p>(1) Dmitrevskaya, O.I.; Sokolov, N.M. <p>AUXILIARY INFORMATION</p>																																																																			
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis; solid state transition temperatures drawn from the heating curves obtained with automatic recording.</p> <p>NOTE:</p> <p>The eutectic composition is given as 100x₂= 49 in the original text, but this figure is conflicting with both the data tabulated and Fig. 1b of the original paper.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Not stated. Component 2 undergoes a phase transition at t_{trs}(2)/°C= 202.</p>																																																																		
	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>																																																																		
	<p>REFERENCES:</p>																																																																		

<p>COMPONENTS:</p> <p>(1) Lithium ethanoate (lithium acetate); LiC₂H₃O₂; [546-89-4]</p> <p>(2) Lithium nitrate; LiNO₃; [7790-69-4]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was submitted to visual polythermal analysis by Diogenov (Ref. 1) as a side of the reciprocal ternary Li, Na/C₂H₃O₂, NO₃, and by Diogenov et al. (Ref. 2), and Sokolov and Tsindrik (Ref. 3) as a side of the reciprocal ternary K, Li/C₂H₃O₂, NO₃. All investigations were restricted to the liquidus.</p> <p>The fusion temperature of component 1 given in Refs. 1, 2 (564 K) is 7 K higher than that (557 K) reported both in Ref. 3 and Table 1 of the Preface. Again for component 1, a solid state transformation is mentioned in Refs. 1, 2 as occurring at 536-538 K, whereas, in a subsequent paper by the same group (Ref. 4), a far different temperature (405 K) is reported. No information about the existence of any solid-solid transition in lithium ethanoate is known to the evaluator from any source (included Ref. 3 and Table 1), but Diogenov's group.</p> <p>The diagrams shown in Refs. 1-3 are qualitatively similar, and characterized by the presence of a single eutectic at 100x₂ about 51. It is, however, a bit surprising that neither Sokolov and Tsindrik (Ref. 3, where Ref. 1 is quoted), nor Diogenov et al. (Ref. 2, where Ref. 1 is not quoted) have commented on the unusually large discrepancies existing between the eutectic temperatures they found (463 K and 449 K, respectively) and the previous value (418 K) by Diogenov (Ref. 1). These discrepancies might be related to the fact that component 1 tends to form glasses.</p> <p>At any rate, the evaluator - due to the apparent lack of internal consistency of the measurements by Diogenov's group - is inclined to attach more reliability to the data from Ref. 3, although regretting that they are reported only in graphical form.</p> <p>REFERENCES:</p> <p>(1) Diogenov, G.G. AUXILIARY INFORMATION																																																																									
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis. Melts contained in a glass tube and stirred. Temperatures measured with a Nichrome-Constantane thermocouple and a 17 mV full scale millivoltmeter. The temperature readings refer to the disappearance of isotropicity in the melt on cooling.	SOURCE AND PURITY OF MATERIALS: Component 1: prepared by reacting aqueous ("chemically pure") Na_2CO_3 with a slight excess of methanoic acid of analytical purity. The solvent and excess acid were removed by heating to 160 °C. Component 2: "chemically pure" material.																																																																								
	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler). REFERENCES:																																																																								

<p>COMPONENTS:</p> <p>(1) Sodium methanoate (sodium formate); NaCHO₂; [141-53-7]</p> <p>(2) Sodium propanoate (sodium propionate); NaC₃H₅O₂ [137-40-6]</p>	<p>ORIGINAL MEASUREMENTS:</p> <p>Sokolov, N.M.; Minchenko, S.P. Zh. Obshch. Khim. 1971, 41, 1656-1659.</p>

<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis supplemented with thermographical analysis.</p> <p>NOTE:</p> <p>The fusion temperature reported for component 1 (531 K) coincides with that listed in Preface, Table 1 (530.7±0.5 K), whereas the T_{trs} values from Ref. 2 and Table 1 are significantly discrepant. Concerning component 2, the fusion temperature (571 K) looks as somewhat too high; moreover, doubts are to be cast about the reliability of the highest transition temperature (560 K) quoted by the authors from Ref. 2, inasmuch as both DSC (Table 1) and adiabatic calorimetry (Table 3 of the Preface) proved the occurrence of solid state transformations only at 467-470 and 491-494 K, respectively.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Both components prepared from the proper acid and the carbonate (Ref. 1). Component 1 melts at t_{fus}(1)/°C= 258 and undergoes a phase transition at t_{trs}(1)/°C= 242 (Ref. 2). Component 2 melts at t_{fus}(2)/°C= 298 (according to Fig.s 3, 4, of the original paper; compiler) or 300 (Fig. 1), and undergoes phase transitions at t_{trs}(2)/°C= 195, 217, 287 (Ref. 2).</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably <u>+2</u> K (compiler).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. Khim. 1954, 24, 1581-1593. (2) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956,</p>

COMPONENTS:

- (1) Sodium methanoate (sodium formate);
 NaCHO_2 ; [141-53-7]
 (2) Sodium butanoate (sodium butyrate);
 $\text{NaC}_4\text{H}_7\text{O}_2$; [156-54-7]

EVALUATOR:

Franzosini, P.,
 Dipartimento di Chimica Fisica,
 Universita' di Pavia (ITALY).

CRITICAL EVALUATION:

This system was studied only by Sokolov (Ref. 1), who suggested the existence of: (i) a eutectic, E_1 , at 525 K (252 °C) and $100x_2 = 2.5$; (ii) a eutectic, E_2 , at 581 K (308 °C) and $100x_2 = 89$; and (iii) an intermediate compound, $\text{Na}_2\text{CHO}_2\text{C}_4\text{H}_7\text{O}_2$, congruently melting at 614 K (341 °C).

Component 2, however, forms liquid crystals. Therefore, the fusion temperature, $T_{\text{fus}}(2) = 603$ K (330 °C; Ref. 1), should be identified with the clearing temperature, the corresponding value from Table 1 of the Preface being $T_{\text{clr}}(2) = 600.4 \pm 0.2$ K. No mention is made by the author of the other phase transitions occurring in component 2, including that corresponding to the actual fusion, viz., $T_{\text{fus}}(2) = 524.5 \pm 0.5$ K (Table 1).

Conversely, the fusion temperature of component 1, $T_{\text{fus}}(1) = 531$ K (258 °C; Ref. 1), satisfactorily corresponds to the value of Table 1, viz., $T_{\text{fus}}(1) = 530.7 \pm 0.5$ K.

In conclusion, Sokolov's assertion of the existence of the congruently melting intermediate compound is a reasonable interpretation of the trend of the available data. In this case, however, the phase diagram could be interpreted with reference to Scheme D.1 of the Preface: in particular, the eutectic E_2 could be actually identified with an M'_E point, Sokolov's diagram likely being similar to that shown in Preface, Scheme D.1.

The unusual size of the dome and the absence of any information about the solidus does not allow one to exclude that Sokolov's points might be at least in part relevant to liquid-liquid instead of solid-liquid equilibria. One might therefore take into account the occurrence of liquid layering as shown in the figure: in particular, the eutectic E_2 could be actually identified with an invariant at which equilibrium occurs among two isotropic liquid and one crystalline liquid phases.

<p>COMPONENTS:</p> <p>(1) Sodium methanoate (sodium formate); NaCHO_2; [141-53-7]</p> <p>(2) Sodium iso.pentanoate (sodium iso.valerate); $\text{Na}i\text{-C}_5\text{H}_9\text{O}_2$; [539-66-2]</p>	<p>EVALUATOR:</p> <p>Franzosini, P., Dipartimento di Chimica Fisica, Università di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1), who claimed the existence of:</p> <p>(i) a eutectic, E_1, at 525 K (252 °C) and $100x_2 = 0.75$; (ii) a eutectic, E_2, at 518 K (245 °C) and $100x_2 = 94.5$; and (iii) an intermediate compound, $\text{Na}_5(\text{CHO}_2)_3(1\text{-C}_5\text{H}_9\text{O}_2)_2$ congruently melting at 593 K (320 °C).</p> <p>Component 2, however, forms liquid crystals. Therefore, the fusion temperature reported in Ref. 1, $T_{\text{fus}}(2) = 535$ K (262 °C) is actually to be identified with the clearing temperature, the corresponding value from Table 2 of the Preface being $T_{\text{clr}}(2) = 559 \pm 1$ K. The remarkable discrepancy between these values might be attributed to the presence of some impurity in Sokolov's sample, inasmuch as the value from Table 2 meets rather satisfactorily those reported by Ubbelohde et al. (556 K; Ref. 2), and by Duruz et al. (553 K; Ref. 3). According to Table 2, component 2 melts at 461.5 ± 0.6 K.</p> <p>Conversely, the fusion temperature reported in Ref. 1 for component 1, $T_{\text{fus}}(1) = 531$ K (238 °C) is in satisfactory agreement with the value from Table 1, viz., $T_{\text{fus}}(1) = 530.7 \pm 0.5$ K.</p> <p>In conclusion, Sokolov's assertion of the existence of the congruently melting intermediate compound is a reasonable interpretation of the trend of the available data. In this case, however, the phase diagram should be modified as follows: the eutectic E_2 should be identified with an M_E^* point, Sokolov's diagram being likely similar to that shown in Scheme D.1.</p> <p>The unusual size of the dome and the absence of any information about the solidus does not allow one to exclude that Sokolov's points might be at least in part relevant to liquid-liquid instead of solid-liquid equilibria. AUXILIARY INFORMATION																																																																									
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis. Melts contained in a glass tube and stirred. Temperatures measured with a Nichrome-Constantane thermocouple and a 17 mV full scale millivoltmeter. The temperature readings refer to the disappearance of isotropy in the melt on cooling.	SOURCE AND PURITY OF MATERIALS: Materials prepared by reacting aqueous ("chemically pure") Na_2CO_3 with a slight excess of the proper acid of analytical purity. The solvent and excess acid were removed by heating to 160 °C. ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler). REFERENCES:

<p>AUXILIARY INFORMATION</p>																																																	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>A Pyrex device, suitable for work under an inert atmosphere, and allowing one to observe the system visually, was employed (for details, see Ref. 1). The initial crystallization temperatures were measured with a Chromel-Alumel thermocouple checked by comparison with a certified Pt resistance thermometer, and connected with a L&N Type K-3 potentiometer.</p> <p>NOTE:</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>C. Erba RP materials, dried by heating under vacuum.</p>																																																
<p>Previous investigations by the same group (Ref. 2) stated that the cryometric constant of sodium methanoate was $K = 9.4 \pm 0.2$ K molality⁻¹, and that</p> $\lim_{m \rightarrow 0} (\Delta T/m) = 9.6 \text{ K molality}^{-1}$ <p>(where ΔT: experimental freezing point depression; m: molality of the solute) when NaCl was the solute. Consequently, the solubility of component 2 in component 1 in the solid state ought to be insignificant.</p>	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 0.1 K (compiler).</p> <p>REFERENCES:</p> <p>(1) Braghetti, M.; Leonesi, D.; Franzosini, P. Ric. Sci. <u>1968</u>, 38, 116-118.</p> <p>(2) Leonesi, D.; Piantoni, G.; Berchiesi, G.; Franzosini, P. Ric. Sci. <u>1968</u>, 38, 702-705.</p>																																																

<p>COMPONENTS:</p> <p>(1) Sodium methanoate (sodium formate); NaCHO₂; [141-53-7]</p> <p>(2) Sodium thiocyanate; NaCNS; [540-72-7]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>The system sodium methanoate - sodium thiocyanate was investigated by Sokolov, 1954 (Ref. 1), Sokolov and Pochtakova, 1958 (Ref. 2), Cingolani et al., 1971 (Ref. 3), and Storonkin et al., 1974 (Ref. 4).</p> <p>The liquidus curve drawn on the basis of visual polythermal observations led Sokolov (Ref. 1) to express the opinion that the system was a eutectic one.</p> <p>Sokolov and Pochtakova (Ref. 2) re-examined the system (as a side of the composition square of the reciprocal ternary K, Na/CHO₂, CNS) using the same method and came to parallel conclusions. It is however to be noted that: (i) differences up to 8 K exist between the fusion temperatures listed in either paper for mixtures of equal composition; and (ii) the coordinates of the eutectic are somewhat different, i.e., 460 K and 100x₂= 36 according to Ref. 1, and 462 K and 100x₂= 38 according to Ref. 2.</p> <p>Cingolani et al. (Ref. 3), not aware of Ref.s 1, 2, found two invariants, viz. a eutectic at 462.7 K and 100x₂= 38.0 (in excellent agreement with Ref. 2) and the other one corresponding to the incongruent melting of the intermediate compound Na₅(CHO₂)₄CNS. They supplemented their visual observations (carried out at a cooling rate of about 0.25 K min⁻¹) with DSC analysis, and, in particular, asserted that the composition of the intermediate compound "was confirmed by DSC measurements". They could also observe in the composition triangle of each of the ternaries Na/Br, CHO₂, CNS, Na/CHO₂, Cl, CNS, and Na/CHO₂, CNS, I a crystallization region belonging to the binary intermediate compound and covering respectively 0.45, 0.80, and 1.80 % of the liquidus area.</p> <p>Storonkin et al. (Ref. 4) employed DTA to investigate the ternary Na/CHO₂, CNS, NO₃, and once more found, for the binary system of interest here, just one eutectic at 443 K and 100x₂= 36; they also claimed the distribution coefficient of NaCHO₂ in NaCNS to be zero in the thiocyanate crystallization field. They were apparently not aware of Ref. 3.</p> <p>Because of the better accuracy of the experimental approach, the evaluator is inclined to recommend (among those available so far) the data by Berchiesi et al. (Ref. 3). The fact that Storonkin et al. (Ref. 4), by employing a DTA technique, were not able to detect the intermediate compound still remains surprising. This fact, however, might be explained if the large supercooling effect found by the latter authors in the region of the ternary eutectic could not be prevented in the region of the binary eutectic. Efficient stirring and slow cooling rate have likely allowed Cingolani et al. (Ref. 3) to avoid this drawback. The presence of some impurity in Storonkin et al. (Ref. 4) methanoate is even possible, inasmuch as their T_{fus}(1)/K value (528) is some 3 K lower than those reported in Ref.s 1 (531), 2 (531), and 3 (530.65), and in Table 3 [530.46±0.04 (adiabatic calorimetry); 530.7±0.5 (DSC)].</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. AUXILIARY INFORMATION																																																																																											
METHOD/APPARATUS/PROCEDURE: Visual method (for details, see Ref. 1). The melts contained in a Pyrex cryostat were cooled at a rate of about 0.25 K/min; the temperatures of initial crystallization were measured with a Chromel-Alumel thermocouple checked by comparison with a certified Pt resistance thermometer, and connected with a L&N potentiometer type K-3. Supplementary DSC measurements were also performed.	SOURCE AND PURITY OF MATERIALS: Materials of stated purity $\geq 99\%$ were employed after careful drying.																																																																																										
	ESTIMATED ERROR: Temperature: accuracy ± 0.05 K (authors).

AUXILIARY INFORMATION																																																																			
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis; salt mixtures melted in a glass tube (surrounded by a wider tube) and stirred with a glass thread. The temperatures of initial crystallization were measured with a Nichrome-Constantane thermocouple checked at the fusion points of water, benzoic acid, mannitol, AgNO_3 , Cd, KNO_3 , and $\text{K}_2\text{Cr}_2\text{O}_7$.	SOURCE AND PURITY OF MATERIALS: "Chemically pure" materials recrystallized from water.																																																																		
NOTE: The fusion temperature of component 1 (531 K) is in excellent agreement with the value (530.7 ± 0.5 K) listed in Table 1 of the Preface, where a solid state transition (at 502 ± 5 K), not mentioned by the author, is also reported.	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler). REFERENCES:																																																																		

<p>COMPONENTS:</p> <p>(1) Sodium methanoate (sodium formate); NaCHO₂; [141-53-7]</p> <p>(2) Sodium nitrate; NaNO₃; [7631-99-4]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>The system sodium methanoate - sodium nitrate was investigated by Sokolov, 1954 (Ref. 1), Tsindrik, 1958 (Ref. 2), Berchiesi et al., 1972 (Ref. 3), and Storonkin et al., 1974 (Ref. 4).</p> <p>The liquidus curve drawn on the basis of visual polythermal observations led Sokolov (Ref. 1) to express the opinion that the formation of any intermediate compound was to be excluded, and consequently the system was a eutectic one.</p> <p>Tsindrik (Ref. 2), who belonged to the same Smolensk Medical Institute (S.M.I.) as Sokolov, re-examined the system (as a side of the composition square of the reciprocal ternary Li, Na/CHO₂, NO₃) using the same method and came to parallel conclusions. Significant discrepancies, however, exist in the trend of the liquidus curves given by either author; and for the coordinates of the eutectic, Tsindrik (Ref. 2) quoted figures (from a paper discussed in 1956 by Sokolov - Ref. 5) which coincide neither with those reported by Sokolov himself in his 1954 paper (Ref. 1) nor with those the evaluator could obtain by plotting Tsindrik's experimental points (Ref. 2).</p> <p>Berchiesi et al. (Ref. 3), being aware of Sokolov's paper (Ref. 1), found two invariant points: a eutectic and one corresponding to the incongruent melting of the intermediate compound Na₄(CHO₂)₃NO₃. They supplemented their visual observations with DSC analysis of four mixtures. In the recorded traces they recognized: for x₁ = 0.7926, "peaks corresponding to the peritectic transition (477 K) and to complete fusion"; for x₁ = 0.7312, "peaks corresponding to the eutectic fusion (464 K), to the peritectic transition (477 K) and to complete fusion"; for x₁ = 0.6560, "peaks corresponding to the eutectic fusion and to the peritectic transition"; for x₁ = 0.5190, one "peak corresponding to the eutectic fusion". They could also observe in the composition triangle of the ternary Na/CHO₂, CNS, NO₃ a crystallization region belonging to the binary intermediate compound and covering 5.30 % of the liquidus area.</p> <p>Storonkin et al. (Ref. 4) employed DTA to investigate the same ternary, and once more found, for the binary system of interest here, just one eutectic although at coordinates different from those reported by Sokolov (Ref. 1) and by Tsindrik (Ref. 2); they also claimed the distribution coefficient of NaCHO₂ in NaNO₃ to be zero in the nitrate crystallization field. Storonkin et al. (Ref. 4) were apparently aware only of a 1971 paper by Sokolov and Khaitina (Ref. 6), where in turn only Sokolov's 1954 findings (Ref. 1) were quoted.</p> <p>Finally, it is to be mentioned that the cryometric data of Leonesi et al., 1968 (Ref. 7), proved that the nitrate has no tendency (or at least a negligibly small tendency) to dissolve in the methanoate in the solid state.</p> <p>In order to evaluate the consistency of the above sets of measurements, the following considerations may be useful.</p> <p>In any binary system where solid solutions are absent, the branch of the liquidus curve rich in component 1 may often be represented satisfactorily by means of the approximate equation (Ref. 8)</p> $T(1) = \{H(1)/R + (A/R)(x_2)^2\} / \{S(1)/R - \ln(x_2)\}$ <p>where A is an empirical constant which of course is zero for ideal systems, and</p> $H(1) = \Delta_{fus}(1)H_m; \quad S(1) = \Delta_{fus}(1)S_m \cdot$ <p>When T(1) is between [T_{fus}(1) and T_{trs}(1)],</p> $H(1) = \Delta_{fus}(1)H_m + \Delta_{trs}(1)H_m; \quad S(1) = \Delta_{fus}(1)S_m + \Delta_{trs}(1)S_m \cdot$ <p>Taking now the DSC numerical values listed in Table 3 of the Preface, which concern component 1, i.e. sodium methanoate, one obtains for the ideal behaviour the curve denoted as "ideal" in the Figure of the next page.</p>	

COMPONENTS:

- (1) Sodium methanoate (sodium formate);
NaCHO₂; [141-53-7]
(2) Sodium nitrate;
NaNO₃; [7631-99-4]

EVALUATOR:

Ferloni, P.,
Dipartimento di Chimica Fisica,
Universita' di Pavia (ITALY).

CRITICAL EVALUATION (continued):

For the system K/CHO₂, NO₃ Leonesi et al. (Ref. 7) were able to fit their experimental points fairly well for the branch rich in methanoate, when A/R was assigned the value -175 K. In the present binary, formed with the common cation Na and the same pair of different anions, it seemed not unreasonable to expect analogous behavior. Introducing into Eq. (1) the above $\Delta(1)H_m$ and $\Delta(1)S_m$ values, and again A/R = -175 K, the "real" curve of the Figure is obtained. It can be seen that Berchiesi et al.'s (Ref. 3) points are the closest to this curves, whereas progressively increasing discrepancies are observed for the data of Tsindrik (Ref. 2), Sokolov (Ref. 1), and Storonkin et al. (Ref. 4) (each temperature being corrected in order to make allowance for the differences in the fusion temperatures of the methanoate given by the different authors).

Thus, the evaluator is inclined to recommend (among those available so far) the data by Berchiesi et al. (Ref. 3). The fact that Storonkin et al. (Ref. 4), by employing a DTA technique, where not able to detect the intermediate compound seems rather surprising. This fact, however, might be related to the large supercooling effect found by the latter authors in the region of the ternary eutectic and difficult to prevent also in the region of the binary eutectic. Efficient stirring and slow cooling rate have likely allowed Berchiesi et al. (Ref. 3) to avoid this drawback. The presence of some impurity in Storonkin et al.'s (Ref. 4) methanoate is even possible, inasmuch as their $T_{fus}(1)/K$ value (528) is some 3 K lower than those reported in Ref.s 1 (531), 2 (531), and 3 (530.65), and in Table 3 [530.46±0.04 (adiabatic calorimetry); 530.7±0.5 (DSC)].

<p>AUXILIARY INFORMATION</p>																																																																			
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p> <p>NOTE:</p> <p>The fusion and solid state transition temperatures reported for component 1 (604 and 527 K, respectively) agree reasonably with the T_{fus}(1) and T_{trs}(1) values (601.3±0.5 and 527±15 K, respectively) listed in Table I of the Preface. Concerning component 2, the fusion temperature (571 K) looks, on the contrary, as somewhat too high; moreover, doubts are to be cast about the reliability of the lowest (350 K) and highest (560 K) transition temperatures quoted by the author from Ref. 2, inasmuch as both DSC (Table 1) and adiabatic calorimetry (Table 3) proved the occurrence of solid state transformations only at 491-494 and 467-470 K, respectively.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: "chemically pure" material; it undergoes a phase transition at t_{trs}(1)/°C= 254 (Ref.1). Component 2: prepared from commercial propanoic acid (distilled before use) and "chemically pure" sodium carbonate; the solid recovered was recrystallized from n-butanol; it undergoes phase transitions at t_{trs}(2)/°C= 77, 195, 217, 287 (Ref. 2).</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably <u>+2 K</u> (compiler).</p>																																																																		
	<p>REFERENCES:</p> <p>(1) Bergman, A.G.; Evdokimova, K.A. <i>Izv. Sektora Fiz.-Khim. Anal.</i> <u>1956</u>, 27, 296-314. (2) Sokolov, N.M.; <i>Tezisy Dokl. X Nauch. Konf. S.M.I.</i> <u>1956</u>.</p>																																																																		

COMPONENTS:

- (1) Sodium ethanoate (sodium acetate);
 $\text{NaC}_2\text{H}_3\text{O}_2$; [127-09-3]
 (2) Sodium butanoate (sodium butyrate);
 $\text{NaC}_4\text{H}_7\text{O}_2$; [156-54-7]

EVALUATOR:

Ferloni, P.,
 Dipartimento di Chimica Fisica,
 Universita' di Pavia (ITALY).

CRITICAL EVALUATION:

The visual polythermal method was employed by Sokolov (Ref. 1) to study the lower boundary of the isotropic liquid field: the results were subsequently reviewed by Sokolov and Pochtakova (Ref. 2). According to these authors, the [congruently melting at 546 K (273 °C)] intermediate compound $\text{Na}_5(\text{C}_2\text{H}_3\text{O}_2)_3(\text{C}_4\text{H}_7\text{O}_2)_2$ is formed, and two invariants exist, i.e., a eutectic E_1 [at 539 K (266 °C), and $100x_2 = 33.5$], and a eutectic E_2 [at 523 K (250 °C), and $100x_2 = 69$].

Component 2, however, forms liquid crystals. Accordingly, the fusion temperature, $T_{\text{fus}}(2) = 603 \text{ K}$ (330 °C), reported in Refs. 1, 2 should be identified with the clearing temperature, $T_{\text{clr}}(2)$, of component 2, the corresponding value from Table 1 of the Preface being $600.4 \pm 0.2 \text{ K}$.

For the same component, Table 1 of the Preface [besides the $T_{\text{clr}}(2)$ value] provides the values 450.4 ± 0.5 , 489.8 ± 0.2 , 498.3 ± 0.3 , and $508.4 \pm 0.5 \text{ K}$ respectively, for $T_{\text{tr}}^{\text{iv}}(2)$ to $T_{\text{tr}}^{\text{I}}(2)$, and $T_{\text{fus}}(2)/K = 524.5 \pm 0.5$. These phase relations, first stated on the basis of DSC records, were subsequently confirmed by Schiraldi and Chioldelli's conductometric results (Ref. 3). Phase transformations are quoted in Ref. 2 from Ref. 4 as occurring at 390, 505, 525, and 589 K, respectively. A comparison of the two sets of data allows one to compare the two intermediate transition temperatures from Ref. 4 with $T_{\text{tr}}^{\text{I}}(2)$ and $T_{\text{fus}}(2)$ from Table 1 of the Preface. Reasonable doubts can be cast, on the contrary, about the actual existence of Ref. 4 highest and lowest transformations (the former - if present - ought to represent the transformation from one liquid crystalline phase into another).

More recently, Prisyazhnyi et al. (Ref. 5) - to whom Refs. 1, 2 seem to be unknown - carried out a derivatographical re-investigation of the system, which allowed them to draw the lower boundaries of both the isotropic liquid, and the liquid crystal field. Their clearing [$T_{\text{clr}}(2) = 598 \text{ K}$ (325 °C)] and fusion [$T_{\text{fus}}(1) = 603 \text{ K}$ (330 °C); $T_{\text{fus}}(2) = 527 \text{ K}$ (254 °C)] temperatures substantially agree with those from Table 1 of the Preface; moreover, it is to be stressed that they do not mention any transition intermediate between $T_{\text{clr}}(2)$ and $T_{\text{fus}}(2)$.

Prisyazhnyi et al.'s, and Sokolov's results (filled and empty circles, respectively) are compared in the figure (IL: isotropic liquid; LC: liquid crystals), an inspection of which allows one to state that: (i) the invariant at about $100x_2 = 70$ is actually an M_E^{I} point, and (ii) a further characteristic point exists (at about $100x_2 = 80$) which escaped Sokolov's attention, and is probably a minimum, m, in a series of solid solutions. Prisyazhnyi et al.'s results suggest at $0 \leq 100x_1 \leq 60$ a behavior similar to that shown in Scheme A.3 of the Preface.

The two two-phase regions pertinent to the liquid crystal - isotropic liquid equilibria, and to solid solutions formation, respectively, might be so narrow as to have prevented Prisyazhnyi et al. to observe two distinct sets of points in each of these regions, whereas one cannot explain the lack of information by the same authors about eutectic fusion at $60 \leq 100x_1 \leq 100$.

AUXILIARY INFORMATION																																																																						
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis. Melts contained in a glass tube and stirred. Temperatures measured with a Nichrome-Constantane thermocouple and a 17 mV full scale millivoltmeter. The temperature readings refer to the disappearance of isotropicity in the melt on cooling.	SOURCE AND PURITY OF MATERIALS: Component 1: "chemically pure" material. Component 2: prepared by reacting aqueous ("chemically pure") Na_2CO_3 with a slight excess of iso.butanoic acid of analytical purity. The solvent and excess acid were removed by heating to 160 °C.																																																																					
	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																																																					
	REFERENCES:																																																																					

<p>COMPONENTS:</p> <p>(1) Sodium ethanoate (sodium acetate); NaC₂H₃O₂; [127-09-3]</p> <p>(2) Sodium pentanoate (sodium valerate); NaC₅H₉O₂; [6106-41-8]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Pochtakova (Ref. 1), who claimed the existence of: (i) a eutectic, E₁, at 537 K (264 °C) and 100x₂= 31.5; (ii) a eutectic, E₂, at 526 K (253 °C) and 100x₂= 54; and (iii) an intermediate compound, Na₃(C₂H₃O₂)₂C₅H₉O₂, congruently melting at 541 K (268 °C).</p> <p>Component 2, however, forms liquid crystals. Therefore, the fusion temperature reported in Ref. 1, T_{fus}(2)= 630 K (357 °C), has to be identified with the clearing temperature, the corresponding value from Table 1 of the Preface being T_{clr}(2)= 631±4 K. This Table provides also T_{fus}(2)= 498±2 K, a figure which can be identified (even if not fully satisfactorily) with that (489 K) corresponding to the highest phase transformation temperature quoted by Pochtakova from Ref. 2. For the same component, Table 1 of the Preface reports no solid state transition, whereas Pochtakova quotes (from Ref. 2) T_{trs}(2)/K= 482 and 453. It is, however, to be stressed that the single transition observed (at 479±1 K) with DTA in sodium n-pentanoate by Duruz et al. (Ref. 3) was no more mentioned in a subsequent DSC investigation by the same group (Ref. 5).</p> <p>Concerning component 1, the fusion temperature, T_{fus}(1)= 604 K (331 °C; Ref. 1), is reasonably identified with the corresponding value from Table 1 of the Preface, viz., 601.3±0.5 K. Allowance being made for the remarkable discrepancy, one might also connect the phase transition quoted from Ref. 2 and occurring at 511 K (238 °C) with that at 527±15 K reported in Table 1 of the Preface. No reasonable correspondence, however, can be hazarded between the other T_{trs} values quoted from Ref. 2 [viz., 403 K (130 °C), 391 K (118 °C), and 331 K (58 °C)] and the superambient T_{trs}'s given in Table 1.</p> <p>On the basis of the available data, the phase diagram of this system could be supposed to be similar to that shown in Scheme D.1 of the Preface, Pochtakova's eutectic E₂ being intended as an M_E point.</p> <p>REFERENCES:</p> <p>(1) Pochtakova, E.I. Zh. Obshch. Khim. 1966, 36, 3-8.</p> <p>(2) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956.</p> <p>(3) Duruz, J.J.; Michels, H.J.; Ubbelohde, A.R. Proc. R. Soc. AUXILIARY INFORMATION																																																																															
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis.	SOURCE AND PURITY OF MATERIALS: Component 1: "chemically pure" material. Component 2: prepared from n-pentanoic acid and the hydrogen carbonate (Ref. 1, where, however, carbonate instead of hydrogen carbonate was employed; compiler). Component 1 undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 58, 118, 130, 238$ (Ref. 2). Component 2 undergoes phase transitions at $t_{\text{trs}}(2)/^\circ\text{C} = 180, 209, 216$ (Ref. 2).																																																																														
ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																																																															
REFERENCES: (1) Sokolov, N.M. <i>Zh. Obshch. Khim.</i> <u>1954</u> , 24, 1581-1593. (2) Sokolov, N.M. <i>Tezisy Dokl. X Nauch. Konf. S.M.I.</i> <u>1956</u>																																																																															

<p>COMPONENTS:</p> <p>(1) Sodium ethanoate (sodium acetate); NaC₂H₃O₂; [127-09-3]</p> <p>(2) Sodium iso.pentanoate (sodium iso.valerate); NaI-C₅H₉O₂; [539-66-2]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied by Sokolov (Ref. 1), and by Pochtakova (Ref. 2) who reviewed Sokolov's results. Both of them suggested the phase diagram to be of the eutectic type, with the invariant point at either 429 K (156 °C) and 100x₂= 73 (Ref. 1), or 433 K (160 °C) and 100x₂= 80.0 (Ref. 2).</p> <p>Component 2, however, forms liquid crystals. Therefore, the fusion temperature, T_{fus}(2)= 535 K (262 °C; Ref. 1) or 533 K (260 °C; Ref. 2), should be identified with the clearing temperature, the corresponding value from Table 2 of the Preface being T_{clr}(2)= 559±1 K. The remarkable discrepancy between the latter value and the former ones might be attributed to some impurity in the samples of the Russian authors, inasmuch as the value from Table 2 meets rather satisfactorily those reported by Ubbelohde et al. (556 K; Ref. 3) and by Duruz et al. (553 K; Ref. 4).</p> <p>For the same component, Pochtakova quotes from Ref. 5 two phase transition temperatures, viz., 451 K (178 °C), and 425 K (152 °C). The higher one can be reasonably identified with the actual fusion temperature, and compared with the value T_{fus}(2)= 461.5±0.6 K reported in Table 2 of the Preface, whereas the lower one has no correspondence in the same Table.</p> <p>Both authors report T_{fus}(1)= 604 K (331 °C; Ref.s 1, 2), which may be satisfactorily identified with the value from Table 1 of the Preface, viz., 601.3±0.5 K. Allowance being made for the discrepancy, one might also connect the phase transition quoted (by Pochtakova) from Ref. 5 as occurring at 511 K (238 °C), with that at 527±15 K reported in Table 1. No reasonable correspondence, however, can be hazarded between the other T_{trs} values quoted by Pochtakova from Ref. 5 [viz., 403 K (130 °C), 391 K (118 °C), and 331 K (58 °C)] and the superambient T_{trs}'s given in Table 1.</p> <p>Taking into account the available experimental data, one may suggest that the phase diagram of this system should not be far from those shown either in Scheme A.1, or in Scheme A.3 of the Preface, the eutectic being actually intended as an M_E point.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: "chemically pure" material. Component 2: prepared from commercial iso.pentanoic acid (distilled twice before use) and the "chemically pure" hydrogen carbonate (Ref. 1). Component 1 undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 58, 118, 130, 238$ (Ref. 2) and melts at $t_{\text{fus}}(1)/^\circ\text{C} = 331$. Component 2 undergoes phase transitions at $t_{\text{trs}}(2)/^\circ\text{C} = 152, 178$ (Ref. 2) and melts at $t_{\text{fus}}(2)/^\circ\text{C} = 260$.</p> <p>ESTIMATED ERROR:</p> <p>Temperature: precision probably ± 2 K (compiler).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <i>Zh. Obshch. Khim.</i> <u>1954</u>, 24, 1581-1593. (2) Sokolov, N.M. <i>Tezisy Dokl. X Nauch. Konf. S.M.I.</i> <u>1956</u>.</p>

<p>COMPONENTS:</p> <p>(1) Sodium ethanoate (sodium acetate); $\text{NaC}_2\text{H}_3\text{O}_2$; [127-09-3]</p> <p>(2) Sodium hexanoate (sodium caproate); $\text{NaC}_6\text{H}_{11}\text{O}_2$; [10051-44-2]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied by Sokolov (Ref. 1), and by Pochtakova (Ref. 2). The former author claims the existence of two eutectics [E_1, at 541 K (268 °C) and $100x_2 = 34.5$; E_2, at 533 K (260 °C) and $100x_2 = 49.5$], and of the intermediate compound $\text{Na}_8(\text{C}_2\text{H}_3\text{O}_2)_5(\text{C}_6\text{H}_{11}\text{O}_2)_3$, which congruently melts at 543 K (270 °C). The latter author claims in turn the existence of a eutectic [at 546 K (273 °C) and $100x_2 = 48.5$], the incongruently melting compound $\text{Na}_5(\text{C}_2\text{H}_3\text{O}_2)_4\text{C}_6\text{H}_{11}\text{O}_2$, and a "perekhodnaya tochka" [at 550 K (277 °C) and $100x_2 = 34.0$].</p> <p>Component 2, however, forms liquid crystals. Therefore, the fusion temperature, $T_{\text{fus}}(2) = 638$ K (365 °C; Ref.s 1, 2), should be identified with the clearing temperature, the corresponding value from Table 1 of the Preface being $T_{\text{clr}}(2) = 639.0 \pm 0.5$ K. The transition temperature $T_{\text{trs}}(2) = 499$ K (226 °C) quoted by Pochtakova from Ref. 3 has in turn to be intended as the fusion temperature, the corresponding value from Table 1 being 499.6 ± 0.6 K.</p> <p>The following point also deserves attention. Two more transitions are quoted in Ref. 2 from Ref. 3 as occurring in component 2 at 615 K (342 °C) and 476 K (203 °C), respectively. The latter agrees with that reported at 473 ± 2 K in Table 1, whereas no evidence was obtained by subsequent investigators (Ref. 4) for a transition comparable with the former one: should it exist, it might mean that two different mesomorphic phases are present in sodium hexanoate.</p> <p>As for component 1, Sokolov and Pochtakova report $T_{\text{fus}}(1) = 603$ K (330 °C) and 604 K (331 °C), respectively, i.e., values which favorably meet that from Table 1 (601.3 ± 0.5 K). For the same component, Pochtakova quotes from Ref. 3 a few other phase transition temperatures, viz., 511 K (238 °C), 403 K (130 °C), 391 K (118 °C), and 331 K (58 °C), of which only the first one finds some correspondence with one of the T_{trs} values from Table 1, i.e., $T_{\text{trs}} = 527 \pm 15$ K.</p> <p>In conclusion, either author's suggestions for the phase diagram require modifications. Indeed, the invariant occurring at 533 K and $100x_2 = 49.5$ (Ref. 1), or at 546 K and $100x_2 = 48.5$ (Ref. 2), should likely be identified with an M_E point, the actual coordinates of which, however, should be verified with better accuracy. Moreover, the composition of the intermediate compound and the nature of the second invariant are not sufficiently supported by the available data, and need as well a further investigation, e.g., by DSC or DTA.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. AUXILIARY INFORMATION																																					
METHOD/APPARATUS/PROCEDURE: DTA. Thermograph with photorecorder. Salt(s) sealed under vacuum in Pyrex ampoules. No other information given.	SOURCE AND PURITY OF MATERIALS: $\text{NaC}_2\text{H}_3\text{O}_2$ of analytical purity and "chemically pure" NaCNS, heated 10-15 h at temperatures 50-60 °C below their fusion temperatures, were employed.																																				
NOTE: This binary was also submitted to visual polythermal analysis by Sokolov (Ref. 1), and Golubeva et al. (Ref. 2). The eutectic composition detected by Storonkin et al. ($100x_2 = 55$) fairly agrees with those reported both in Ref. 1 (54.5) and Ref. 2 (55.5). Sokolov's eutectic temperature (517 K), on the contrary, is significantly higher than those given both by Storonkin et al. (507 K) and Golubeva et al. (509 K; Ref. 2).	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler). REFERENCES: (1) Sokolov, N.M. Zh. Obshch. Khim. <u>1954</u> , 24, 1150-1156. (2) Golubeva, M.S.; Aleshkina, N.N.; Bergman, A.G.; Zh. AUXILIARY INFORMATION																																																																			
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis; salt mixtures melted in a glass tube (surrounded by a wider tube) and stirred with a glass thread. The temperatures of initial crystallization were measured with a Nichrome-Constantane thermocouple checked at the fusion points of water, benzoic acid, mannitol, AgNO_3 , Cd, KNO_3 , and $\text{K}_2\text{Cr}_2\text{O}_7$. NOTE: The fusion temperature (604 K) of component 1 can be identified with the $T_{\text{fus}}(1)$ value (601.3±0.5 K) listed in Preface, Table 1. The coordinates of the eutectic (500-501 K and $100x_2 = 65$) are in reasonable agreement with those reported by both Bergman and Evdokimova (497 K and $100x_2 = 66$; Ref. 1), and by Sokolov et al. (499 K and $100x_2 = 65$; Ref. 2).	SOURCE AND PURITY OF MATERIALS: "Chemically pure" materials recrystallized from water. ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler). <p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis supplemented with differential thermal analysis.</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p> <p>NOTE:</p> <p>Concerning component 1: (1) the fusion temperature (603 K) can be identified with the $T_{\text{fus}}(1)$ value (601.3+0.5 K) listed in Preface Table 1; and (1i) among the solid state transition temperatures (331, 391, 403, and 511 K) quoted by the authors from Ref. 1, only the third and fourth ones find some correspondence in the T_{trs} values listed in Table 1. The coordinates of the eutectic (499 K and $100x_2 = 65$) are in reasonable agreement with those previously reported by both Bergman and Evdokimova (497 K and $100x_2 = 66$; Ref. 3), and Sokolov (500-501 K and $100x_2 = 65$; Ref. 4).</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Not stated.</p> <p>Component 1 undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 58, 118, 180, 288$ (Ref. 1; the figures 180, 288 are most probably misprints, inasmuch as the same authors quoting the same source report 130, 238 in several other papers; compiler).</p> <p>Component 2 undergoes a phase transition at $t_{\text{trs}}(2)/^\circ\text{C} = 170$ (Ref. 2).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M.; <i>Tezisy Dokl. X Nauch. Konf. S.M.I.</i> 1956. (2) Bergman, A.G.; Berul', S.I.; <i>Izv. Sektora Fiz.-Khim. Anal.</i> 1958, 21, 178-183. (3) Bergman, A.G.; Evdokimova, K.A.; <i>Izv. Sektora Fiz.-Khim. Anal., Inst. Obshchei i Neorg. Khim. Akad. Nauk SSSR</i> 1956, 27, 296-314. (4) Sokolov, N.M.; <i>Zh. Obshch. Khim.</i> 1957, 27, 840-844 (*); <i>Russ. J. Gen. Chem. (Engl. Transl.)</i> 1957, 27, 917-920.</p>

<p>COMPONENTS:</p> <p>(1) Sodium ethanoate (sodium acetate); NaC₂H₃O₂; [127-09-3]</p> <p>(2) Sodium nitrate; NaNO₃; [7631-99-4]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>The system Na/C₂H₃O₂, NO₃ was studied by Sokolov (Ref. 1), Bergman and Evdokimova (as a side of the reciprocal ternary K, Na/C₂H₃O₂, NO₃; Ref. 2), Diogenov (as a side of the reciprocal ternary Li, Na/C₂H₃O₂, NO₃; Ref. 2), Gimel'shtein and Diogenov (as a side of the reciprocal ternary Cs, Na/C₂H₃O₂, NO₃; Ref. 4), Storonkin et al. (as a side of the ternary Na/C₂H₃O₂, CNS, NO₃; Ref. 5), and Diogenov and Chumakova (as a side of the reciprocal ternary K, Na/C₂H₃O₂, NO₃; Ref. 6). The visual polythermal analysis, and DTA were employed in Ref.s 1-4 and 6, and in Ref. 5, respectively; moreover, in Ref. 4, X-ray diffraction patterns were taken on some compositions.</p> <p>The fusion temperature of component 1 should be 604, 599, 610, 600, 601, and 599 K according to Ref.s 1,2,3,4,5, and 6, respectively, the corresponding value listed in Preface, Table 1 being 601.3± 0.5 K. For the same component, a solid state transition is reported by Ref.s 2, 3, and 4. The transition temperatures given by Ref.s 2 and 4 (527 and 543 K, respectively) can be identified with the T_{trs(1)} value (527±15 K) listed in Table 1 of the Preface, whereas no reliability is to be attached to Diogenov's figures (596 K; Ref.3) which has no correspondence in Table 1, and, moreover, was not confirmed in subsequent investigations by the same group (Ref. 4).</p> <p>Diogenov (Ref. 3) claimed the existence of two intermediate compounds, i.e.: (i) Na₃(C₂H₃O₂)₂NO₃, incongruently melting, with a peritectic at 539 K and 100x₂= 38.5; and (ii) Na₅C₂H₃O₂(NO₃)₄, congruently melting, with a distectic at 545 K. In the evaluator's opinion, however, the discontinuities Diogenov (Ref. 3) found on either branch of his liquidus are relevant rather to the occurrence of solid state transitions in either component, than to the formation of any intermediate compound. In fact, in their re-investigations of the binary Na/C₂H₃O₂, NO₃ neither Gimel'shtein and Diogenov (who supplemented their visual observations with some X-ray diffraction patterns; Ref. 4), nor Diogenov and Chumakova (Ref. 6) could confirm Diogenov's former point.</p> <p>Therefore, the system can be safely classified as of the eutectic type, with the invariant at 494±4 K and 100x₂ at about 58.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. ^a T/K values calculated by the compiler.

Characteristic point(s):

Peritectic, P, at 266 °C (author) and 100x₂ = 38.5 (compiler).
Eutectic, E₁, at 225 °C and 100x₂ = 57.5 (author).
Eutectic, E₂, at about 268 °C and 100x₂ about 82.5 (compiler).

Intermediate compound(s):

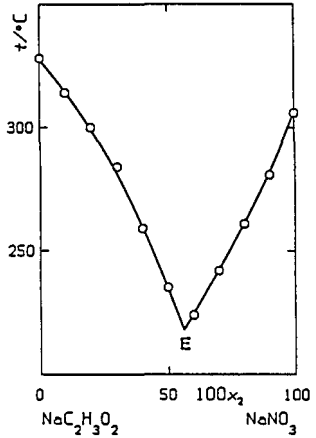

Na₃(C₂H₃O₂)₂NO₃, incongruently melting (author).
Na₅C₂H₃O₂(NO₃)₄, congruently melting at 272 °C (author).

Note - On the branch rich in component 1 an inflexion at 323 °C corresponds to a phase transition of NaC₂H₃O₂.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis.	SOURCE AND PURITY OF MATERIALS: Not stated.
	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).

<p>AUXILIARY INFORMATION</p>																																																													
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis. Salt(s) melted in a test tube. Temperature measured with a Nichrome-Constantane thermocouple and a millivoltmeter with mirror reading to 17 mV.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1 synthesized from propanoic acid and NaHCO_3. Commercial component 2 further purified by the author according to Laiti.</p>																																																												
<p>NOTE:</p> <p>The fusion temperature of component 1 (571 K) is somewhat too high: both DSC and adiabatic calorimetry provide a value close to 562 K (see Preface, Table 3).</p>	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <i>Zh. Obshch. Khim.</i> <u>1954</u>, 24, 1581-1593.</p>																																																												

COMPONENTS: (1) Sodium butanoate (sodium butyrate); $\text{NaC}_4\text{H}_7\text{O}_2$; [156-54-7] (2) Sodium iso.butanoate (sodium iso.butyrate); $\text{NaI.C}_4\text{H}_7\text{O}_2$; [996-30-5]	EVALUATOR: Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).																																																																								
CRITICAL EVALUATION: <p>The system was studied only by Sokolov (Ref. 1), who claimed the existence of a continuous series of solid solutions, with a minimum at 494 K and $100x_2=72.5$.</p> <p>Component 1, however, forms liquid crystals in a stability field ranging between $T_{\text{clr}}(1)/\text{K}=600.4\pm 0.2$ and $T_{\text{fus}}(1)/\text{K}=524.5\pm 0.5$ (according to Preface, Table 1). Consequently: (i) Sokolov's fusion temperature of component 1 (603 K) should be identified with the clearing temperature; (ii) at low values of $100x_2$, Sokolov's points should refer to the formation of liquid crystals (pseudo-liquidus), and not of solid solutions (true liquidus). Besides the minimum, m, an M point should exist (although its coordinates are hard to detect on the basis of the available data, and the phase diagram should be not too different from that shown in Scheme B.3 of the Preface.</p> REFERENCES (1) Sokolov, N.M.; Zh. Obshch. Khim. 1954, 24, 1581-1593.

METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis. Melts contained in a glass tube and stirred. Temperatures measured with a Nichrome-Constantane thermocouple and a 17 mV full scale millivoltmeter. The temperature readings refer to the disappearance of isotropy in the melt on cooling.	SOURCE AND PURITY OF MATERIALS: Materials prepared by reacting aqueous ("chemically pure") Na_2CO_3 with a slight excess of the proper acid of analytical purity. The solvent and excess acid were removed by heating to 160 °C.																																																																								
ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																																																									

<p>COMPONENTS:</p> <p>(1) Sodium butanoate (sodium butyrate); $\text{NaC}_4\text{H}_7\text{O}_2$; [156-54-7]</p> <p>(2) Sodium iso.pentanoate (sodium iso.valerate); $\text{Na}i.\text{C}_5\text{H}_9\text{O}_2$; [539-66-2]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1), who suggests a eutectic phase diagram, the invariant point being at 530 K (257 °C) and $100x_2 = 90.5$. Both components, however, form liquid crystals.</p> <p>Therefore, the fusion temperatures, $T_{\text{fus}}(1)=603$ K (330 °C) and $T_{\text{fus}}(2)=535$ K (262 °C), should be identified with the clearing temperatures, the corresponding values from Tables 1, 2 of the Preface being $T_{\text{clr}}(1)=600.4+0.2$ K, and $T_{\text{clr}}(2)=559+1$ K, respectively. The discrepancy between the values concerning component 2 might be attributed to some impurity of Sokolov's samples, inasmuch as the value from Preface (Table 2) meets rather satisfactorily those reported by Ubbelohde et al. (556 K; Ref. 2) and by Duruz et al. (553 K; Ref. 3). No mention is made by the author of other phase transitions occurring in either component, including those corresponding to the actual fusion, which should be $T_{\text{fus}}(1)=524+0.5$ K (Preface, Table 1) and $T_{\text{fus}}(2)=461.5+0.5$ K (Table 2).</p> <p>Accordingly, the phase diagram of the system should be modified. The available data do not allow one to rule out neither of the following possibilities: (i) the eutectic point should be identified with a minimum point in a continuous series of liquid crystal solutions; (ii) the eutectic point should be identified with an M''_E point, at which the isotropic liquid should be in equilibrium with two liquid crystal solutions of different composition (Preface, Scheme C.3, Fig. 3.3).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <i>Zh. 	ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).																																																																								

<p>COMPONENTS:</p> <p>(1) Sodium butanoate (sodium butyrate); NaC₄H₇O₂; [156-54-7]</p> <p>(2) Sodium hexanoate (sodium caproate); NaC₆H₁₁O₂; [10051-44-2]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1), who claimed the existence of two eutectics [E₁, at 590 K (317 °C) and 100x₂= 22.5; E₂, at 590 K (317 °C) and 100x₂= 27.5], and of the intermediate compound Na₄(C₄H₇O₂)₃C₆H₁₁O₂, congruently melting at 594 K (321 °C).</p> <p>Both components, however, form liquid crystals. Therefore, Sokolov's fusion temperatures, T_{fus}(1)= 603 K (330 °C) and T_{fus}(2)= 638 K (365 °C), should be identified with clearing temperatures, the corresponding values from Preface, Table 1 being T_{clr}(1)= 600.4±0.2 K and T_{clr}(2)= 639.0±0.5 K, respectively.</p> <p>No mention is made by the author of other phase transitions of either component, including those corresponding to their actual fusions, which ought to occur at T_{fus}(1)= 524.5±0.5 K and T_{fus}(2)= 499.6±0.6 K, respectively (see Table 1).</p> <p>Concerning the phase diagram, the available data suggest the following interpretations as possible. If the maximum at 594 K (321 °C) and 100x₂= 25 does exist, Sokolov's eutectics could be identified with either M_E' points at the opposite sides of the distectic pertinent to a congruently melting intermediate compound (Preface, Scheme D.2), or m points in a situation similar to that shown in Scheme C.3. Conversely, if the occurrence of the maximum is considered as insufficiently proved, one might think of the existence of either an M_E" point (with limited series of liquid crystal solutions on both sides; Scheme C.2), or a (single) minimum in a continuous series of liquid crystal solutions.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <p>AUXILIARY INFORMATION</p>																																																	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis. Melts contained in a glass tube and stirred. Temperatures measured with a Nichrome-Constantane thermocouple and a 17 mV full scale millivoltmeter. The temperature readings refer to the disappearance of isotropicity in the melt on cooling.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: prepared by reacting aqueous ("chemically pure") Na_2CO_3 with a slight excess of n-butyric acid of analytical purity. The solvent and excess acid were removed by heating to 160 °C. Component 2: "chemically pure" material.</p>																																																
<p>NOTE:</p> <p>Component 1 forms liquid crystals. Therefore Sokolov's fusion temperature, $T_{\text{fus}}(1) = 603 \text{ K}$, should be identified with the clearing temperature, the corresponding value in Table 1 of the Preface being $600.4 \pm 0.2 \text{ K}$. It is hard to infer the topology of the system from the available data: indeed, the phase diagram might be similar to that shown in Preface, Scheme A.1, but other possibilities remain open.</p>	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably $\pm 2 \text{ K}$ (compiler).</p> <p>REFERENCES:</p>																																																

<p>COMPONENTS:</p> <p>(1) Sodium butanoate (sodium butyrate); NaC₄H₇O₂; [156-54-7]</p> <p>(2) Sodium octadecanoate (sodium stearate); NaC₁₈H₃₅O₂; [822-16-2]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1) who employed the visual polythermal analysis to draw the lower boundary of the isotropic liquid field. From the shape of this boundary, he concluded that the intermediate compound Na₅(C₄H₇O₂)₃(C₁₈H₃₅O₂)₂ [congruently melting at 663 K (390 °C)] was formed, and that the limits of the stability field of this compound were a eutectic at 521 K (248 °C) and 100x₂= 15, and a "perekhodnaya tochka" at 582 K (309 °C) and 100x₂= 96.5.</p> <p>Actually, both components form liquid crystals, the liquid crystalline phases being one for component 1 (see Preface, Table 1), and two for component 2 (see Table 4 of the Preface). Sokolov's fusion temperatures, T_{fus}(1)= 603 K (330 °C), and T_{fus}(2)= 581 K (308 °C), consequently should be identified with the clearing temperatures, the corresponding values from Tables 1 and 4 being 600.4±0.2 and 552.7 K, respectively.</p> <p>Since the complete topology of the binary can hardly be interpreted from the available data, it is more realistic to list here the few points which, in the evaluator's opinion, seem to be sufficiently reliable.</p> <p>(i) At intermediate compositions it seems reasonable to assume that a continuous series of liquid crystal solutions is formed, with an azeotrope at 663 K and 100x₂= 40.</p> <p>(ii) Accordingly, the left hand section (0 ≤ 100x₂ ≤ 40) of the phase diagram might be interpreted with reference to Preface, Scheme C.2: in this case, Sokolov's eutectic should be identified with an M_E point.</p> <p>Conversely, no definite interpretation of the phase diagram at high 100x₂ values seems possible. Indeed, it is not clear how Sokolov could argue the occurrence of an invariant (the "perekhodnaya tochka" at 100x₂= 96.5) from the trend of his experimental data which does not support unambiguously any significant slope change of the curve in this region. Moreover, Sokolov's "fusion" temperature of component 2 (581 K) looks as fully unreliable, being 18 K higher than the second highest T_{clr} value determined during the last 30 years (Ref. 2), and 28 K higher than the clearing temperature listed in Table 4 of the Preface.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <p>REFERENCES:</p>																																																																															

<p>COMPONENTS:</p> <p>(1) Sodium butanoate (sodium butyrate); NaC₄H₇O₂; [156-54-7]</p> <p>(2) Sodium thiocyanate; NaCNS; [540-72-7]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1), who restricted his visual polythermal investigation to the lower boundary of the isotropic liquid field. He asserted the existence of the intermediate compound Na₄(C₄H₇O₂)₃CNS, which melts incongruently at 541 K (268 °C), and of a eutectic at 535 K (262 °C) and 100x₂ = 48.5.</p> <p>Component 1, however, forms liquid crystals, which are stable between T_{fus}(1) = 524.5 ± 0.5 K and T_{clr}(1) = 600.4 ± 0.2 (see Preface, Table 1). Sokolov's fusion temperature (603 K) consequently should be identified with the clearing temperature, whereas the T_{trs} value (525 K), reported by the same author in a subsequent paper (Ref. 2), is in close agreement with the fusion temperature given in Table 1.</p> <p>In the evaluator's opinion, Sokolov's findings are not sufficient to prove unambiguously the existence of the intermediate compound. Consequently, more than one interpretation can be given for the topology of this binary.</p> <p>Indeed, if the compound does exist:</p> <p>(i) the phase diagram could be similar to that shown in Preface, Scheme D.3, (ii) Sokolov's "Perekhodnaya tochka" should to be identified with an M_p point; and (iii) the occurrence of a (so far undetected) M_E point is required.</p> <p>If, on the contrary, one assumes that the intermediate compound does not exist, Sokolov's invariant at 541 K and 100x₂ = 31.5 might be connected with the fusion of component 1 in the way shown in Scheme B.2 of the Preface.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1) who restricted his polythermal investigation to the lower boundary of the isotropic liquid field. He claimed that an intermediate compound, i.e., $\text{Na}_4(\text{C}_4\text{H}_7\text{O}_2)_3\text{NO}_2$, exists which forms eutectics with either pure component at 590 K (317 °C) and $100x_2 = 17.5$, and at 347 K (274 °C) and $100x_2 = 96$, respectively.</p> <p>No data on the solidus are available, and consequently the existence of the intermediate compound is not fully proved. Nevertheless, the evaluator is inclined to accept - at least in part - Sokolov's interpretation of the topology of the system.</p> <p>It must, however, be specified that, due to the fact that component 1 forms liquid crystals stable between 524.5±0.5 K and 600.4±0.2 K (see Preface, Table 1), (i) the first eutectic at 590 K ought to be identified with an M_E point; and (ii) a further (so far undetected) invariant, presumably an M_E point, should exist.</p> <p>In conclusion, the phase diagram ought to be similar to that shown in Scheme D.1 of the Preface.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. COMPONENTS:

- (1) Sodium butanoate (sodium butyrate);
NaC₄H₇O₂; [156-54-7]
- (2) Sodium nitrate;
NaNO₃; [7631-99-4]

EVALUATOR:

Ferloni, P.,
Dipartimento di Chimica Fisica,
Universita' di Pavia (ITALY).

CRITICAL EVALUATION:

The visual polythermal method was employed by Dmitrevskaya (Ref. 1) [see also Sokolov, (Ref. 2)] to study the lower boundary of the isotropic liquid field: according to this author, an incongruently melting intermediate compound of probable composition Na₄(C₄H₇O₂)₃NO₃ is formed, and two invariants exist, i.e., a eutectic, E [at 540 K (267 °C), and 100x₂ = 50], and a "perekhodnaya tochka", P² [at 549 K (276 °C), and 100x₂ = 27].

Component 1, however, forms liquid crystals. Accordingly, the fusion temperature, T_{fus}(1) = 603 K (330 °C), reported in Ref. 1 should be identified with the clearing temperature, T_{clr}(1), of component 1, the corresponding value from Preface, Table 1 being 600.4 ± 0.2 K.

For the same component, Table 1 of the Preface [besides the T_{clr}(1) value] provides four solid state transitions (at 450.4 ± 0.5, 489.8 ± 0.2, 498.3 ± 0.3, and 508.4 ± 0.5) and T_{fus}(1)/K = 524.5 ± 0.5. These phase relations, first stated on the basis of DSC records, were subsequently confirmed by Schiraldi and Chiodelli's conductometric results (Ref. 3). Phase transformations are quoted in Ref. 1 from Ref. 4 as occurring at 390, 505, 525, and 589 K, respectively. A comparison of the two sets of data allows one to identify the two intermediate transition temperatures from Ref. 4 with the first T_{trs}(2) and T_{fus}(2) from Table 1. Reasonable doubts can be raised, on the contrary, about the actual existence of Ref. 4 highest transition (which - if present - should represent the transformation from a liquid crystalline phase into another one) and of the lowest transformations.

More recently, Prisyazhnyi et al. (Ref. 5) - to whom Refs. 1, 2 seem to be unknown - carried out a derivatographical re-investigation of the system, which allowed them to draw the lower boundaries of both the isotropic liquid, and the liquid crystal field. Concerning component 1, their clearing [T_{clr}(1) = 599 K (326 °C)] and fusion [T_{fus}(1) = 526 K (253 °C)] temperatures substantially agree with those from Table 1 of the Preface; it is moreover to be stressed that they do not mention any transition intermediate between T_{clr}(1) and T_{fus}(1).

Prisyazhnyi et al.'s, and Dmitrevskaya's results (filled and empty circles, respectively) are compared in the figure (IL: isotropic liquid; LC: liquid crystals), an inspection of which allows one to make the following remarks. An invariant exists, which escaped Dmitrevskaya's attention, and is reasonably to be classified as an M_E point. Moreover, the invariant at about 100x₂ = 25 is actually an M' point: its abscissa being known only approximately, it can hardly be decided if it is of the M_E or of the M_P type: in the former case, the complete phase diagram should be similar to Scheme D.1 of the Preface; in the latter one, to Scheme D.3.

The two-phase region pertinent to the liquid crystal - isotropic liquid equilibria might be so narrow as to have prevented Prisyazhnyi et al. to observe two distinct sets of points in this region, whereas the lack of information by the same authors about eutectic fusion in the different samples studied by derivatographical analysis remains rather surprising.

<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The heating and cooling traces were recorded in an atmosphere of purified argon with an OD-102 derivatograph (MOM, Hungary) working at a rate of $6-8 \text{ K min}^{-1}$, and using Al_2O_3 as the reference material. Temperatures were measured with a Pt/Pt-Rh thermocouple. A hot-stage Amplival polarizing microscope was employed to detect the transformation points from the liquid crystalline into the isotropic liquid phase.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Not stated. Component 1: $t_{\text{fus}}(1)/^\circ\text{C}$ about 253; $t_{\text{clr}}(1)/^\circ\text{C}$ about 326 (compiler). Component 2: $t_{\text{fus}}(2)/^\circ\text{C}$ about 308 (compiler).</p>
	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy is not evaluable (compiler).</p>
	<p>REFERENCES:</p>

<p>COMPONENTS:</p> <p>(1) Sodium iso.butanoate (sodium iso.butyrate); NaI.C₄H₇O₂; [996-30-5]</p> <p>(2) Sodium iso.pentanoate (sodium iso.valerate); NaI.C₅H₉O₂; [539-66-2]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1), who claimed the existence of a continuous series of solid solutions, with a minimum at 461-462 K and 100x₂= 50.</p> <p>The fusion temperature of component 1 (533 K) is not far from that reported in Preface, Table 2 (526.9±0.7 K).</p> <p>Component 2, however, forms liquid crystals in a stability field ranging between T_{clr}(2)/K= 559±1 and T_{fus}(2)/K= 461.5±0.6 (according to Table 2).</p> <p>Consequently, Sokolov's fusion temperature of component 2 should reasonably be identified as the clearing temperature of this component. Its value, i.e., 535 K, is remarkably lower than that listed in Table 2, i.e., 559±1 K: the latter figure, however, meets rather satisfactorily those reported by Ubbelohde et al. (556 K; Ref. 2), and by Duruz et al. (553 K; Ref. 3), so that the discrepancy might be attributed to insufficient purity of Sokolov's sample (indeed, due to the - usually small - value of the enthalpy change associated with clearing, a small amount of impurities is often sufficient to cause a dramatic drop of the clearing temperature).</p> <p>Many of Sokolov's points should represent isotropic liquid - liquid crystal, rather than isotropic liquid - solid equilibria.</p> <p>Details of the phase diagram, however, are hard to be inferred from the available data.</p>

<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1) who restricted his visual polythermal investigations to the lower boundary of the isotropic liquid field; and claimed the existence of a single eutectic at 433 K (160 °C) and $100x_2 = 23.5$:</p> <p>Component 2, however, forms liquid crystals which are stable between 639.0+0.5 K and 499.6+0.6 K (see Preface, Table 1). Consequently, the fusion temperature 638 K (365°C; Ref. 1) should be identified with the clearing temperature, and Sokolov's outline of the phase diagram is incomplete. In particular, at least two invariants should exist, although the available data do not allow one to state with certainty their nature.</p> <p>The following hypotheses can be tentatively suggested.</p> <p>(i) Sokolov's invariant should be considered as an M_E point; a second one (an M_E point so far undetected) should exist at a lower temperature and at a higher x_2 value.</p> <p>(ii) Sokolov's invariant is actually a eutectic, E, and a second invariant (an M_p point so far undetected) should exist at higher temperature and at a higher x_2 value.</p> <p>If hypothesis (i) is the correct one, the phase diagram ought to be similar to that shown in Scheme A.2 of the Preface.</p> <p>However, taking into account that $T_{\text{fus}}(2)$ (499.6+0.6 K; Table 1 of the Preface) is significantly higher than the fusion temperature of Sokolov's invariant, and that the enthalpy change pertinent to fusion is usually much larger than that pertinent to clearing, the evaluator is inclined to prefer hypothesis (ii). Reference should be therefore made to Preface, Scheme B.1 or B.2.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. Khim. <u>1954</u>, 24, 1581-1593.</p>

COMPONENTS:

- (1) Sodium iso.butanoate (sodium iso.butyrate);
 $\text{Na}(\text{C}_4\text{H}_7\text{O}_2)$; [996-30-5]
 (2) Sodium octadecanoate (sodium stearate);
 $\text{NaC}_{18}\text{H}_{35}\text{O}_2$; [822-16-2]

EVALUATOR:

Ferloni, P.,
 Dipartimento di Chimica Fisica,
 Universita' di Pavia (ITALY).

CRITICAL EVALUATION:

This system was studied only by Sokolov (Ref. 1) who employed the visual polythermal analysis to draw the lower boundary of the isotropic liquid field. From the shape of this boundary, he concluded that the intermediate compound $\text{Na}_5(\text{C}_4\text{H}_7\text{O}_2)_2(\text{C}_{18}\text{H}_{35}\text{O}_2)_3$ [congruently melting at 596 K (323 °C)] was formed, and that the limits of the stability field of this compound were a eutectic at 435 K (162 °C) and $100x_2 = 25.5$, and a "perekhodnaya tochka" at 584 K (311 °C) and $100x_2 = 94.5$.

Component 2, however, forms liquid crystals. Thence, the fusion temperature by Sokolov, viz., $T_{\text{fus}}(2) = 581 \text{ K}$ (308 °C), should be identified with the clearing temperature and compared with the $T_{\text{clr}}(2)$ value reported in Preface, Table 4 (552.7 K). Conversely, Sokolov's $T_{\text{fus}}(1)$ [533 K (260 °C)] seems sufficiently reliable, being not far from the value (526.9 ± 0.7 K) reported in Table 2 of the Preface.

In the evaluator's opinion, the phase diagram at $0 \leq 100x_2 \leq 60$ is to be reconsidered, e.g., with reference to Preface, Scheme A.2: Sokolov's eutectic could be an M_E point, whereas the maximum at $100x_2 = 60$ could represent an azeotrope.

On the contrary, no definite interpretation of the phase diagram at high $100x_2$ values seems possible. Indeed, it is not clear how Sokolov could argue the occurrence of an invariant (the "perekhodnaya tochka" at $100x_2 = 94.5$) from the trend of his experimental data which does not unambiguously support any significant slope change of the curve in this region. Moreover, Sokolov's "fusion" temperature of component 2 (581 K) looks as fully unreliable, being 18 K higher than the second highest T_{clr} value determined during the last 30 years (Ref. 2), and 28 K higher than the clearing temperature listed in Table 4 of the Preface.

<p>AUXILIARY INFORMATION</p>																																																																			
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis; salt mixtures melted in a glass tube (surrounded by a wider tube) and stirred with a glass thread. The temperatures of initial crystallization were measured with a Nichrome-Constantane thermocouple checked at the fusion points of water, benzoic acid, mannitol, AgNO$_3$, Cd, KNO$_3$, and K$_2$Cr$_2$O$_7$.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: prepared from "chemically pure" sodium hydrogen carbonate (carbonate in the reference quoted; compiler) and commercial iso.butanoic acid distilled before use (Ref. 1); the salt recovered was recrystallized from n-butanol. Component 2: "chemically pure" material recrystallized from water.</p>																																																																		
<p>NOTE:</p> <p>The author does not comment on the minimum at 548 K and 100x$_2$ = 75. A possible explanation might be that liquid layering occurs: in this case, the points at 25 \leq 100x$_2$ \leq 75 should represent liquid-liquid instead of solid-liquid equilibria, the monotectic temperature being 548 K. It is worth mentioning that stratification was reported by the same author in the same paper for the binary Na/i.C$_5$H$_9$O$_2$, NO$_2$.</p>	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably \pm2 K (compiler).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <p>EXPERIMENTAL VALUES:</p> <p>Characteristic point(s):</p> <p>The paper reports - <i>inter alia</i> - on a refinement of the title binary, previously studied by one of the authors (Ref. 1). According to the present investigation, the coordinates of the eutectic are:</p> <p>Eutectic, E, at 220 °C and 100x₂ = 25 (authors).</p>	
<p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p> <p>NOTE:</p> <p>Concerning component 1, no mention is made in Table 2 of solid state phase transformations, although three transitions are quoted by the authors (from Ref. 3), at 493, 364, and 340 K (220, 91, and 67 °C), respectively. Duruz et al. (Ref. 4) report in turn T^{trs}(1) = 493 K (in agreement with the highest transition temperature from Ref. 3), and T^{trs}(1) = 468 K (a figure which has no correspondence in Ref. 3). Finally, Ferloni et al. (Ref. 5) are inclined to think that Sokolov's transformation at 340 K (Ref. 3) actually represents a transition of a hydrated form of the salt.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1 synthesized from iso.butanoic acid and Na₂CO₃ (Ref. 2). "Chemically pure" component 2 recrystallized.</p> <p>Component 1 undergoes phase transitions at t_{trs}(1)/°C = 67, 91, 220 (Ref. 3). Component 2 undergoes a phase transition at t_{trs}(2)/°C = 270 (current literature).</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ±2 K (compiler).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. Khim. 1954, 24, 1150-1156.</p> <p>(2) Sokolov, N.M. Zh. Obshch. Khim. 1954, 24, 1581-1593.</p> <p>(3) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956.</p> <p>(4) Duruz, J.J.; Michels, H.J.; Ubbelohde, A.R. Proc. Roy. Soc. London 1971, A 322, 281-299.</p> <p>(5) Ferloni, P.; Sanesi, M.; Tonelli, P.L.; Franzosini, P. Z. Naturforsch. 1978, A 33, 240-242.</p>

<p>COMPONENTS:</p> <p>(1) Sodium pentanoate (sodium valerate); NaC₅H₉O₂; [6106-41-8]</p> <p>(2) Sodium thiocyanate; NaCNS; [540-72-7]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY) .</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied by Sokolov (Ref. 1) and by Sokolov and Khaitina (Ref. 2): in both papers the visual polythermal investigation was restricted to the lower boundary of the isotropic liquid field. The authors claimed the existence of a 1:1 intermediate compound which melts congruently at 564 K (291 °C; Ref. 1), and forms eutectics with either pure component, at eutectics at 562 K (289 °C) and 100x₂= 46, and at 560 K (287 °C) and 100x₂= 56.5 or 55, respectively.</p> <p>Component 1, however, forms liquid crystals, which are stable between 498+2 K and 631+4 K (Preface, Table 1). The latter value fairly agrees with the fusion temperature (630 K) given in Ref. 1 and 2; the former can be identified (even if not fully satisfactorily) with that (489 K) corresponding to the highest phase transformation temperature quoted by Ref. 2 from Ref. 3. Once more for component 1, Table 1 reports no solid state transition, whereas Sokolov and Khaitina quote (from Ref. 3) T_{trs}(2)/K= 482 and 453. It is, however, to be stressed that the single transition observed (at 479+1 K) with DTA in sodium n-pentanoate by Duruz et al. (Ref. 4) was not more mentioned in a subsequent DSC investigation by the same group (Ref. 5).</p> <p>In the evaluator's opinion, therefore,</p> <p>i) the invariant at 562 K (289 °C) and 100x₂= 46 should be identified with an M_E point,</p> <p>ii) a (so far undetected) M_E invariant should exist within the composition range between M_E and pure component 1, and</p> <p>iii) the phase diagram ought to be similar to that shown in Scheme D.1 of the Preface, but for the fact that the liquid crystal-isotropic liquid diphasic field exhibits a maximum.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <p>COMPONENTS:</p> <p>(1) Sodium pentanoate (sodium valerate); $\text{NaC}_5\text{H}_9\text{O}_2$; [6106-41-8]</p> <p>(2) Sodium nitrite; NaNO_2; [7632-00-0]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied only by Sokolov (Ref. 1) who, on the basis of his visual polythermal observations, claimed the phase diagram to be of the eutectic type, the invariant occurring at 555 K (282 °C) and $100x_1 = 0.04$. This investigation was restricted to the range $0 \leq 100x_1 \leq 55$, because of decomposition of mixtures richer in component 1.</p> <p>Component 1, however, forms liquid crystals. Thence, Sokolov's $T_{\text{fus}}(1)$ [i.e., 610 K (357°C)] should be identified with a clearing temperature, and compared with the value $T_{\text{clr}}(1) = 631 \pm 4$ K reported in Preface, Table 1.</p> <p>The topology of the phase diagram has therefore to be reconsidered with reference to Preface, Schemes A, among which, however, the available data, unfortunately, do not allow one to make a definite choice.</p> <p>Anyway, Sokolov's invariant should be an M_E point and not a conventional eutectic.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis; salt mixtures melted in a glass tube (surrounded by a wider tube) and stirred with a glass thread. The temperatures of initial crystallization were measured with a Nichrome-Constantane thermocouple checked at the fusion points of water, benzoic acid, mannitol, AgNO₃, Cd, KNO₃, and K₂Cr₂O₇.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Component 1: prepared from "chemically pure" sodium hydrogen carbonate (carbonate in the reference quoted; compiler) and commercial pentanoic acid distilled before use (Ref. 1); the salt recovered was recrystallized from n-butanol; $t_{\text{fus}}(1)/^\circ\text{C} = 357$.</p> <p>Component 2: "chemically pure" material recrystallized from water.</p> <p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. Khim. 1954, 24, 1581-1593.</p>																																							

<p>COMPONENTS:</p> <p>(1) Sodium pentanoate (sodium valerate); $\text{NaC}_5\text{H}_9\text{O}_2$; [6106-41-8]</p> <p>(2) Sodium nitrate; NaNO_3; [7631-99-4]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied by Sokolov (Ref. 1), and by Sokolov and Khaïtina (Ref. 2). In both cases, the visual polythermal analysis was employed to detect the lower boundary of the isotropic liquid field. Accordingly, the authors claimed that a 1:1 intermediate compound forms, which melts congruently at 568 K (295 °C), and gives eutectics with either component. Concerning the precise location of these invariants, some values given in the text of the original papers should be corrected with a closer inspection of the pertinent figures. The correct values seem therefore to be $T = 564$ K (291 °C) and $100x_2 = 40.5$ (Ref. 2), and $T = 554$ K (281 °C) and $100x_2 = 58.5$, respectively.</p> <p>Component 1, however, forms liquid crystals, which are stable between 498+2 K and 631+4 K (Preface, Table 1). The latter value fairly agrees with the fusion temperature (630 K) given in Ref. 1 and 2; the former can be identified (even if not fully satisfactorily) with that (489 K) corresponding to the highest phase transformation temperature quoted by Ref. 3. Once more for component 1, Table 1 reports no solid state transition, whereas Sokolov quotes (Ref. 3) $T_{\text{trs}}(1)/K = 482$ and 453. It is, however, to be stressed that the single transition observed (at 479+1 K) with DTA in sodium n-pentanoate by Duruz et al. (Ref. 4) was no more mentioned in a subsequent DSC investigation by the same group (Ref. 5).</p> <p>Taking into account the above remarks, the eutectic at 564 K (291°C) and $100x_2 = 40.4$ ought to be an M_E^* point, and the occurrence of a further invariant (so far undetected and probably an M_E point) is to be expected. The phase diagram could be similar to that shown in Scheme D.1 of the Preface, but for the fact that the liquid crystal-isotropic liquid field is splitted into two parts by a maximum.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. <p>AUXILIARY INFORMATION</p>	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Not stated. Component 1 undergoes phase transitions at $t_{\text{trs}}(1)/^\circ\text{C} = 180, 209, 216$ (Ref. 1) and melts at $t_{\text{fus}}(1)/^\circ\text{C} = 356$. Component 2 undergoes a phase transition at $t_{\text{trs}}(2)/^\circ\text{C} = 275$ (current literature value), and melts at $t_{\text{fus}}(2)/^\circ\text{C} = 308$.</p>
<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably ± 2 K (compiler).</p>	
<p>REFERENCES:</p> <p>(1) Sokolov, N.M. Tezisy Dokl. X Nauch. Konf. S.M.I. 1956.</p>	

<p>COMPONENTS:</p> <p>(1) Sodium iso.pentanoate (sodium iso.valerate); $\text{Na} \cdot \text{C}_5\text{H}_9\text{O}_2$; [539-66-2]</p> <p>(2) Sodium hexanoate (sodium caproate); $\text{NaC}_6\text{H}_{11}\text{O}_2$; [10051-44-2]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1), who claimed that a continuous series of solid solutions is formed, with a minimum, m, at 512 K (239 °C), and $100x_2 = 20$.</p> <p>Both components, however, form liquid crystals (see Preface, Tables 2, 1). Therefore, Sokolov's fusion temperatures, $T_{\text{fus}}(1)/\text{K} = 535$ (262 °C) and $T_{\text{fus}}(2)/\text{K} = 638$ (365 °C), should be identified with clearing temperatures, the corresponding data from Tables 2 and 1 being 559 ± 1 K and 639.0 ± 0.5 K, respectively.</p> <p>Concerning component 1, the remarkable discrepancy might be attributed to insufficient purity of Sokolov's sample, inasmuch as the value from Table 2 (559 ± 1) meets rather satisfactorily those reported by Ubbelohde et al. (556 K; Ref. 2), and by Duruz et al. (553 K; Ref. 3). Indeed, due to the - usually small - value of the enthalpy change associated with clearing, very small amounts of impurities are often sufficient to cause a dramatic drop of the clearing temperature.</p> <p>A continuous series of liquid crystal (instead of solid) solutions should form, and the complete phase diagram should be similar to that shown in Scheme C.1 of the Preface, with a common minimum of the curves limiting the isotropic liquid - liquid crystal diphasic field.</p>

<p>AUXILIARY INFORMATION</p>																																																																									
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Visual polythermal analysis. Melts contained in a glass tube and stirred. Temperatures measured with a Nichrome-Constantane thermocouple and a 17 mV full scale millivoltmeter. The temperature readings refer to the disappearance of isotropicity in the melt on cooling.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>Materials prepared by reacting aqueous ("chemically pure") Na₂CO₃ with a slight excess of either iso.pentanoic or n-hexanoic acid of analytical purity. The solvent and excess acid were removed by heating to 160 °C.</p>																																																																								
	<p>ESTIMATED ERROR:</p> <p>Temperature: accuracy probably <u>+2</u> K (compiler).</p>																																																																								
	<p>REFERENCES:</p>																																																																								

<p>COMPONENTS:</p> <p>(1) Sodium iso.pentanoate (sodium iso.valerate); $\text{NaI.C}_5\text{H}_9\text{O}_2$; [539-66-2]</p> <p>(2) Sodium benzoate; $\text{NaC}_7\text{H}_5\text{O}_2$; [532-32-1]</p>	<p>EVALUATOR:</p> <p>Spinolo, G., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY) .</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied only by Sokolov (Ref. 1), who restricted his polythermal analysis to the lower boundary of the isotropic liquid field, and claimed the existence of a eutectic at 534 K (261 °C) and $100x_2 = 3$.</p> <p>Component 1, however, forms liquid crystals [at $T_{\text{fus}}(1) = 461.5 \pm 0.6$ K; Preface, Table 2] before being transformed in a clear melt. Therefore, Sokolov's fusion temperature, (535 K) should be identified with the clearing temperature, the corresponding value from Table 2 being 559 ± 1 K. The latter figure is remarkably higher than that given by Ref. 1, and it agrees rather satisfactorily with those reported by Ubbelohde et al. (556 K, Ref. 2) and by Duruz et al. (553 K, Ref. 3).</p> <p>Thus, in the evaluator's opinion, the phase diagram could be more correctly interpreted with reference to Scheme A.1 of the Preface, and Sokolov's eutectic should be identified with an M_E point.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. AUXILIARY INFORMATION																																																							
METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis. Melts contained in a glass tube and stirred. Temperatures measured with a Nichrome-Constantane thermocouple and a 17 mV full scale millivoltmeter. The temperature readings refer to the disappearance of isotropy in the melt on cooling.	SOURCE AND PURITY OF MATERIALS: Component 1: prepared by reacting aqueous ("chemically pure") Na_2CO_3 with a slight excess of iso.pentanoic acid of analytical purity. The solvent and excess acid were removed by heating to 160 °C. Component 2: "chemically pure" material.																																																						
	ESTIMATED ERROR: Temperature: accuracy probably <u>+2</u> K (compiler).																																																						
	REFERENCES:																																																						

<p>COMPONENTS:</p> <p>(1) Sodium iso.pentanoate (sodium iso.valerate); $\text{Na} \cdot \text{C}_5\text{H}_9\text{O}_2$; [539-66-2]</p> <p>(2) Sodium octadecanoate (sodium stearate); $\text{NaC}_{18}\text{H}_{35}\text{O}_2$; [822-16-2]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1) who employed the visual polythermal analysis to draw the lower boundary of the isotropic liquid field. From the shape of this boundary, he concluded that the intermediate compound $\text{Na}_3(\text{C}_5\text{H}_9\text{O}_2)(\text{C}_{18}\text{H}_{35}\text{O}_2)_2$ [congruently melting at 596 K (323 °C)] was formed, and that the limits of the stability field of this compound were a eutectic at 413 K (140 °C) and $100x_2 = 17.3$, and a "perekhodnaya tochka" at 582 K (309 °C) and $100x_2 = 93.5$.</p> <p>Actually, both components form liquid crystals, the liquid crystalline phases being one for component 1 (see Preface, Table 2), and two for component 2 (see Preface, Table 4). Therefore, Sokolov's fusion temperatures, $T_{\text{fus}}(1) = 535 \text{ K}$ (262 °C), and $T_{\text{fus}}(2) = 581 \text{ K}$ (308 °C), should be identified with clearing temperatures, the corresponding values from Tables 2 and 4 being 559±1 and 552.7 K, respectively.</p> <p>At intermediate compositions it seems reasonable to assume that a continuous series of liquid crystal solutions is formed, with an azeotrope at 596 K and $100x_2 = 70$. Accordingly, the left hand section ($0 < 100x_2 < 70$) of the phase diagram might be interpreted with reference to Scheme C.2 of the Preface: in this case, Sokolov's eutectic should be intended as an M_E point, allowance being made for the fact that Sokolov's "fusion" temperature of component 1 is 24 K lower than the relevant T_{clr} value listed in Table 2, i.e., 559±1 K. It is, however, to be stressed that the latter figure agrees rather satisfactorily with those reported by Ubbelohde et al. (556 K; Ref. 3) and by Duruz et al. (553 K; Ref. 4).</p> <p>Conversely, no definite interpretation of the phase diagram at high $100x_2$ values seems possible. Indeed, it is not clear how Sokolov could argue the occurrence of an invariant (the "perekhodnaya tochka" at $100x_2 = 93.5$) from the trend of his experimental data which does not unambiguously support any significant slope change of the curve in this region. Moreover, Sokolov's "fusion" temperature of component 2 (581 K) looks as fully unreliable, being 18 K higher than the second highest T_{clr} value determined during the last 30 years (Ref. 2), and 28 K higher than the clearing temperature listed in Table 4.</p>

	<p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. Khim. 1954, 24, 1581-1593.</p>																																													

<p>COMPONENTS:</p> <p>(1) Sodium iso.pentanoate (sodium iso.valerate) $\text{Na} \cdot \text{C}_5\text{H}_9\text{O}_2$; [539-66-2]</p> <p>(2) Sodium nitrate; NaNO_3; [7631-99-4]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This binary was studied by visual polythermal and thermographical analysis by Sokolov (Ref. 1), and Dmitrevkaya and Sokolov (Ref. 2), respectively, with substantially analogous results. The phase diagram was claimed by these authors to be of the eutectic type with the invariant at either 527 K (254 °C) and $100x_1 = 31$ (Ref. 1), or 526 K (253 °C) and $100x_1 = 31.5$ (Ref. 2).</p> <p>Component 1, however, forms liquid crystals. Consequently, the fusion temperature, $T_{\text{fus}}(1) = 535$ K (262°C; Ref.s 1, 2) should be identified with the clearing temperature, the corresponding value from Table 2 of the Preface being 559+1 K. The latter figure is remarkably higher than that by the above mentioned investigators, and agrees rather satisfactorily with those reported by Ubbelohde et al. (556 K; Ref. 3) and by Duruz et al. (553 K; Ref. 4).</p> <p>For the same component: (i) the transition at 451 K (178 °C) quoted in Ref. 2 from Ref. 5 should be identified with the actual fusion temperature, the corresponding value from Table 2 being 461.5+0.6 K, whereas (ii) the transition at 425 K (152 °C) also quoted in Ref. 2 from Ref. 5 has no correspondence in Table 2.</p> <p>Thus the whole phase diagram should be re-interpreted, e.g., with reference to Scheme A.2 of the Preface. In particular, the invariant at 526 K and $100x_1 = 31.5$ should be an M'_E point and not a conventional eutectic.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. Zh. Obshch. COMPONENTS:

- (1) Sodium hexanoate (sodium caproate);
 $\text{NaC}_6\text{H}_{11}\text{O}_2$; [10051-44-2]
 (2) Sodium benzoate;
 $\text{NaC}_7\text{H}_5\text{O}_2$; [532-32-1]

EVALUATOR:

Spinolo, G.,
 Dipartimento di Chimica Fisica,
 Universita' di Pavia (ITALY).

CRITICAL EVALUATION:

This binary was studied only by Sokolov (Ref. 1), who restricted his polythermal investigation to the lower boundary of the isotropic liquid field, and claimed the existence of a "perekhodnaya tochka" (P) at 644 K (371 °C) and $100x_2 = 13$.

Component 1, however, forms liquid crystals [above $T_{\text{fus}}(1) = 499.6 \pm 0.6$ K; Table 1 of the Preface] before turning into a clear melt. Sokolov's fusion temperature (638 K) should be consequently identified with the clearing temperature, the corresponding value from Table 1 being 639.0 ± 0.5 K.

Sokolov's P point at $100x_2 = 13$ corresponds to a slightly marked minimum of the data listed in Ref. 1: the experimental temperature values at $5 < 100x_2 < 15$ actually range between 642 and 647 K, i.e. approximately within the accuracy limits estimated by the compiler.

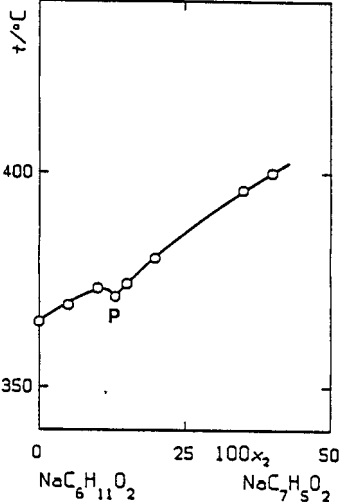

If the temperature differences between the maximum at 646 K (and $100x_2 = 10$) and the P point at 644 K is thought to be meaningful, the phase diagram could be interpreted with reference to Scheme A.2 of the Preface: accordingly, Sokolov's invariant should be identified with an M_E^* point).

If, on the contrary, the above mentioned temperature difference is thought to be meaningless, reference can be made to the front figure, where Sokolov's data are reported. In this case a peritectic equilibrium should exist (at about 644 K) among a liquid crystal, an isotropic liquid and a solid crystal. Accordingly, Sokolov's P point should be identified with an M_P^* point, and a further invariant should exist, e.g. an M_E at $T \leq T_{\text{fus}}(1)$.

<p>COMPONENTS:</p> <p>(1) Sodium hexanoate (sodium caproate); Na C₆H₁₁O₂; [10051-44-2]</p> <p>(2) Sodium octadecanoate (sodium stearate); Na C₁₈H₃₅O₂; [822-16-2]</p>	<p>EVALUATOR:</p> <p>Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).</p>
<p>CRITICAL EVALUATION:</p> <p>This system was studied only by Sokolov (Ref. 1) who employed the visual polythermal analysis to draw the lower boundary of the isotropic liquid field. From the shape of this boundary, he concluded that the intermediate compound Na₅(C₆H₁₁O₂)₂(C₁₈H₃₅O₂)₃ [congruently melting at 602 K (329 °C)] was formed, and that the limits of the stability field of this compound were a eutectic at 512 K (239 °C) and 100x₂= 17.5, and a "perekhodnaya tochka" at 587 K (314 °C) and 100x₂= 94.5.</p> <p>Actually, both components form liquid crystals, the liquid crystalline phases being one for component 1 (see Table 1 of the Preface), and two for component 2 (see Table 4 of the Preface). Sokolov's fusion temperatures, T_{fus}(1)= 638 K (365 °C), and T_{fus}(2)= 581 K (308 °C), are consequently to be identified with the clearing temperatures, the corresponding values from Tables 1 and 4 being 639.0±0.5 and 552.7 K, respectively.</p> <p>Since the complete topology of the binary can hardly be interpreted from the data available, it is more realistic to list here the few points which, in the evaluator's opinion, seem to be sufficiently reliable.</p> <p>(i) At intermediate compositions it seems reasonable to assume that a continuous series of liquid crystal solutions is formed, with an azeotrope at 602 K and 100x₂= 60.</p> <p>(ii) Accordingly, the left hand section (0 < 100x₂ < 60) of the phase diagram might be interpreted with reference to Scheme C.2 of the Preface: in this case, Sokolov's eutectic should be intended as an M_E point.</p> <p>Conversely, no definite interpretation of the phase diagram at high 100x₂ values seems possible. Indeed, it is not clear how Sokolov could argue the occurrence of an invariant (the "perekhodnaya tochka" at 100x₂= 94.5) from the trend of his experimental data which does not unambiguously support any significant slope change of the curve in this region. Moreover, Sokolov's "fusion" temperature of component 2 (581 K) looks as fully unreliable, being 18 K higher than the second highest T_{clr} value determined during the last 30 years (Ref. 2), and 28 K higher than the clearing temperature listed in Table 4.</p> <p>REFERENCES:</p> <p>(1) Sokolov, N.M. ^a T/K values calculated by the compiler.

Characteristic point(s):
 Eutectic, E, at 295 °C and $100x_2 = 63$ (author).

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE: Visual polythermal analysis. Salt(s) melted in a test tube. Temperature measured with a Nichrome-Constantane thermocouple and a millivoltmeter with mirror reading to 17 mV.	SOURCE AND PURITY OF MATERIALS: Component 1 synthesized from n-hexanoic acid and NaHCO_3 . Component 2 of analytical purity recrystallized once from water and once from ethanol.
ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler).	

COMPONENTS: (1) Sodium hexanoate (sodium caproate); $\text{NaC}_6\text{H}_{11}\text{O}_2$; [10051-44-2] (2) Sodium nitrate; NaNO_3 ; [7631-99-4]	EVALUATOR: Ferloni, P., Dipartimento di Chimica Fisica, Universita' di Pavia (ITALY).
CRITICAL EVALUATION: <p>This binary was studied only by Sokolov (Ref. 1), who restricted his polythermal investigation to the lower boundary of the isotropic liquid field, and claimed the existence of a eutectic at 560 K (287 °C) and $100x_2 = 56.5$, and the occurrence of liquid layering at 576 K (302 °C) and $100x_2 > 60$.</p> <p>Component 1, however, forms liquid crystals [at $T_{\text{fus}}(1) = 499.6 \pm 0.6$ K; Preface, Table 1] before turning into a clear melt. Sokolov's fusion temperature (638 K) is consequently to be identified with the clearing temperature, the corresponding value from Table 1 being 639.0 ± 0.5 K. Therefore, in the evaluator's opinion, the phase diagram could be more correctly interpreted with reference to Scheme A.2 of the Preface, allowance being made for the fact that a liquid-liquid miscibility gap impinges on the liquidus branch richer in the higher melting component (NaNO_3). Consequently, Sokolov's eutectic should be an M_E point.</p> REFERENCES: (1) Sokolov, N.M.; Zh. Obshch. Khim. 1954, 24, 1150-1156.

<p>CRITICAL EVALUATION:</p>	
<p>This binary was studied for the first time by Gimel'shtein and Diogenov (Ref. 1) who reported the lower boundary of the isotropic liquid region in the reciprocal ternary $\text{Na, Rb/C}_2\text{H}_3\text{O}_2, \text{NO}_3$ on the basis of visual polythermal observations. They claimed the existence of the intermediate compound $\text{Rb}_3(\text{C}_2\text{H}_3\text{O}_2)_2\text{NO}_3$ (congruently melting at 475 K [202 °C]) and of two eutectics, E_1, at 471 K (198 °C) and $100x_1 = 81.5$, and E_2, at 454 K (181 °C) and $100x_1 = 35.5$.</p> <p>In a subsequent paper on the reciprocal ternary $\text{Cs, Rb/C}_2\text{H}_3\text{O}_2, \text{NO}_3$ (Ref. 2), the same Authors reported refined values of the coordinates of the second eutectic (467 K [194 °C] and $100x_1 = 33$), obtained with the same experimental approach. The new data suggest that those reported in Ref. 1 should be affected by a systematic error (as high as 13 K) in the composition range $20 \leq 100x_1 \leq 50$.</p>	
<p>The system was once more investigated by Gimel'shtein (Ref. 3) who directly measured with D.T.A. the temperatures of the characteristic points previously inferred by the shape of the liquidus. Besides a substantial agreement with the findings of Ref. 2, he reported two more solid state transitions of pure RbNO_3, at 437 and 505 K. Moreover, the existence of an intermediate compound was more reliably proved by a comparison of the X-ray powder pattern of an intermediate mixture, which showed diffraction lines not pertinent to either pure component.</p>	
<p>Finally, the composition of the compound was adjusted by Diogenov, Erylkov and Gimel'shtein (Ref. 4) during an investigation of the reciprocal ternary $\text{Li, Rb/C}_2\text{H}_3\text{O}_2, \text{NO}_3$ with coupled visual polythermal and thermographical analysis. According to this paper, the compound has a 1:1 composition and congruently melts at 476 K (203 °C) and the eutectics are at 467 K (194 °C) and $100x_1 = 33.5$ and at 471 K (198 °C) and $100x_1 = 82$, respectively.</p>	
<p>In spite of the lack of any comment by the Authors on their previous results, the evaluator is inclined to recommend the last interpretation as the more reliable. The figure reports phase boundaries drawn accordingly. On the same figure, the two sets of experimental data, available in numerical form (the visual polythermal data from Ref. 1 and the thermographical data from Ref. 3), have also been plotted as open and full circles, respectively. As a further remark, the melting and transition points of component 1 reported on Ref.s 1-4 reasonably match the most recent literature data: $T_{\text{fus}}(1) = 510, 515, 514, 514, 509$; $T_{\text{trg}}(1) = 498$ (Ref. 5). For what concerns the phase transitions of component 2, reference can be made to the recent work by Kennedy et al. (Ref. 6 and the bibliography therein quoted).</p>

AUXILIARY INFORMATION																																																																																																	
METHOD/APPARATUS/PROCEDURE: Differential thermal analysis (using a derivatograph with automatic recording of the heating curves) and room temperature X-ray diffractometry (using a URS-501M apparatus) were employed. X-ray patterns were taken at $100x_2=40$.	SOURCE AND PURITY OF MATERIALS: Not stated. Component 1 melts at $t_{\text{fus}}/^\circ\text{C}=235$, and undergoes a phase transition at $t/^\circ\text{C}=206$. Component 2 melts at $t_{\text{fus}}/^\circ\text{C}=315$, and undergoes phase transitions at $t/^\circ\text{C}=164, 216, 232, 285$. ESTIMATED ERROR: Temperature: accuracy probably ± 2 K (compiler). Heptanoic acid, potassium salt	
+ nitrous acid, potassium salt	203
Hexanoic acid, potassium salt	
+ acetic acid, potassium salt	E163,164
+ hexanoic acid, sodium salt	E128,129
+ nitrous acid, potassium salt	202
Hexanoic acid, sodium salt	
+ acetic acid, sodium salt	E253, 254, 255
+ benzoic acid, sodium salt	E324, 325
+ butanoic acid, sodium salt	E280, 281
+ butanoic acid, 2-methyl-, sodium salt	E311, 312
+ hexanoic acid, potassium salt	E128, 129
+ nitric acid, sodium salt	329
+ octadecanoic acid, sodium salt	E326, 327
+ propanoic acid, 2-methyl-, sodium salt	E294, 295
+ thiocyanic acid, sodium salt	328
Nitric acid, cesium salt	
+ acetic acid, cesium salt	E134, 134,135
Nitric acid, lithium salt	
+ acetic acid, lithium salt	E210, 211-213
+ butanoic acid, lithium salt	217
+ formic acid, lithium salt	208
+ propanoic acid, lithium salt	215
Nitric acid, potassium salt	
+ acetic acid, potassium salt	170, 171
+ butanoic acid, potassium salt	E187, 188
+ butanoic acid, 2-methyl-, potassium salt	E199, 200, 201
+ formic acid, potassium salt	E159, 151,152
+ pentanoic acid, potassium salt	E195,196
+ propanoic acid, 2-methyl-, potassium salt	E187, 188
Nitric acid, rubidium salt	
+ acetic acid, rubidium salt	E332, 333-335
Nitric acid, sodium salt	
+ acetic acid, sodium salt	E267, 268-272
+ butanoic acid, sodium salt	E289, 290, 291
+ butandioic acid, 2-methyl-, sodium salt	E321, 322, 323
+ formic acid, sodium salt	E326, E237, 238-241
+ hexanoic acid, sodium salt	329
+ pentanoic acid, sodium salt	E308, 309, 310
+ propanoic acid, 2-methyl-, sodium salt	301, 302
+ propanoic acid, sodium salt	276
Nitrous acid, cesium salt	
+ acetic acid, cesium salt	133
Nitrous acid, potassium salt	
+ acetic acid, potassium salt	E172, 173
+ butanoic acid, potassium salt	E185, 186
+ butanoic acid, 2-methyl-, potassium salt	E197, 198
+ formic acid, potassium salt	149
+ heptanoic acid, potassium salt	203
+ hexanoic acid, potassium salt	202
+ nonanoic acid, potassium salt	205
+ octanoic acid, potassium salt	204
+ pentanoic acid, potassium salt	E193, 194
+ propanoic acid, potassium salt	181, 182
+ propanoic acid, 2-methyl-, potassium salt	E189, 190
Nitrous acid, sodium salt	
+ acetic acid, sodium salt	264-266
+ formic acid, sodium salt	235
+ butandioic acid, 2-methyl-, sodium salt	E319, 320
+ butanoic acid, sodium salt	E287, 288
+ pentanoic acid, sodium salt	E306, 307
+ propanoic acid, sodium salt	275
+ propanoic acid, 2-methyl-, sodium salt	300
Nonanoic acid, potassium salt	
+ nitrous acid, potassium salt	205

Octadecanoic acid, sodium salt	
+ benzoic acid, sodium salt	E330, 331
+ butanoic acid, sodium salt	E283, 284
+ butanoic acid, 2-methyl-, sodium salt	E315, 316
+ hexanoic acid, sodium salt	E326, 327
+ propanoic acid, 2-methyl-, sodium salt	E297, 298
Octanoic acid, potassium salt	
+ nitrous acid, potassium salt	204
Pentanoic acid, magnesium salt	
+ pentanoic acid, potassium salt	E123, 124
Pentanoic acid, potassium salt	
+ acetic acid, potassium salt	E159, 160
+ nitric acid, potassium salt	E195, 196
+ nitrous acid, potassium salt	E193, 194
+ pentanoic acid, sodium salt	E121, 122
Pentanoic acid, sodium salt	
+ acetic acid, sodium salt	E248, 249
+ nitric acid, sodium salt	E308, 309, 310
+ nitrous acid, sodium salt	E306, 307
+ pentanoic acid, magnesium salt	E123, 124
+ pentanoic acid, potassium salt	E121, 122
+ thiocyanic acid, sodium salt	E303, 304, 305
Phosphoric acid, magnesium salt	
+ propanoic acid, potassium salt	98
+ propanoic acid, sodium salt	E103, 104
Potassium bromide	
+ acetic acid, potassium salt	137, 138
+ formic acid, potassium salt	136
Potassium chloride	
+ acetic acid, potassium salt	165, 166
+ formic acid, potassium salt	141, 144
Potassium iodide	
+ acetic acid, potassium salt	170, 171
+ formic acid, potassium salt	148
Propanoic acid, 2-methyl-, potassium salt	
+ acetic acid, potassium salt	E157, 158
+ formic acid, potassium salt	E142, 143
+ nitric acid, potassium salt	E191, 192
+ nitrous acid, potassium salt	E189, 190
+ propanoic acid, 2-methyl-, sodium salt	E119, 120
Propanoic acid, 2-methyl-, sodium salt	
+ acetic acid, sodium salt	247
+ benzoic acid, sodium salt	296
+ butanoic acid, sodium salt	E277, E278, 279
+ butanoic acid, 2-methyl-, sodium salt	E292, 293
+ formic acid, sodium salt	225
+ hexanoic acid, sodium salt	E294, 295
+ nitric acid, sodium salt	301, 302
+ nitrous acid, sodium salt	300
+ octadecanoic acid, sodium salt	E297, 298
+ propanoic acid, 2-methyl-, potassium salt	E119, 120
+ thiocyanic acid, sodium salt	299
Propanoic acid, lithium salt	
+ nitric acid, lithium salt	215
+ propanoic acid, potassium salt	97
Propanoic acid, potassium salt	
+ acetic acid, potassium salt	140, 153
+ propanoic acid, lithium salt	97
+ propanoic acid, magnesium salt	98
+ propanoic acid, sodium salt	E99, 100-102
+ nitrous acid, potassium salt	181, 182
+ thiocyanic acid, potassium salt	180
Propanoic acid, sodium salt	
+ acetic acid, sodium salt	242
+ formic acid, sodium salt	222
+ nitric acid, sodium salt	276
+ nitrous acid, sodium salt	278
+ propanoic acid, magnesium salt	E103, 104

Propanoic acid, sodium salt	
+ propanoic acid, potassium salt	E99, 100-102
+ thiocyanic acid, sodium salt	273-274
Sodium bromide	
+ acetic acid, sodium salt	219, 220
+ formic acid, sodium salt	218
Sodium chloride	
+ formic acid, sodium salt	228
+ acetic acid, sodium salt	257, 258
Sodium iodide, sodium salt	
+ acetic acid, sodium salt	202, 263
Thiocyanic acid, lithium salt	
+ acetic acid, lithium salt	209
+ butanoic acid, lithium salt	216
+ formic acid, lithium salt	207
Thiocyanic acid, potassium salt	
+ acetic acid, potassium salt	E167, 168, 169
+ butanoic acid, potassium salt	E183, 184
+ propanoic acid, potassium salt	180
Thiocyanic acid, sodium salt	
+ butanoic acid, 2-methyl-, sodium salt	E317, 318
+ hexanoic acid, sodium salt	328
+ pentanoic acid, sodium salt	E303, 304, 305
+ acetic acid, sodium salt	259-261
+ butanoic acid, sodium salt	285-286
+ formic acid, sodium salt	E229, 230-233
+ propanoic acid, 2-methyl-, sodium salt	299
+ propanoic acid, sodium salt	273-274
Thiocyanic acid, potassium salt	
+ formic acid, potassium salt	E145, 146, 147

Page numbers preceded by E refer to evaluation texts whereas page numbers not preceded by E refer to compiled tables.

SOLUBILITY DATA SERIES

- Volume 1 H. L. Clever, *Helium and Neon*
- Volume 2 H. L. Clever, *Krypton, Xenon and Radon*
- Volume 3 M. Salomon, *Silver Azide, Cyanide, Cyanamides, Cyanate, Selenocyanate and Thiocyanate*
- Volume 4 H. L. Clever, *Argon*
- Volume 5/6 C. L. Young, *Hydrogen and Deuterium*
- Volume 7 R. Battino, *Oxygen and Ozone*
- Volume 8 C. L. Young, *Oxides of Nitrogen*
- Volume 9 W. Hayduk, *Ethane*
- Volume 10 R. Battino, *Nitrogen and Air*
- Volume 11 B. Scrosati and C. A. Vincent, *Alkali Metal, Alkaline Earth Metal and Ammonium Halides. Amide Solvents*
- Volume 12 C. L. Young, *Sulfur Dioxide, Chlorine, Fluorine and Chlorine Oxides*
- Volume 13 S. Siekierski, T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Nitrates*
- Volume 14 H. Miyamoto, M. Salomon and H. L. Clever, *Alkaline Earth Metal Halates*
- Volume 15 A. F. M. Barton, *Alcohols with Water*
- Volume 16/17 E. Tomlinson and A. Regosz, *Antibiotics: I. β -Lactam Antibiotics*
- Volume 18 O. Popovych, *Tetraphenylborates*
- Volume 19 C. L. Young, *Cumulative Index: Volumes 1-18*
- Volume 20 A. L. Horvath and F. W. Getzen, *Halogenated Benzenes, Toluenes and Phenols with Water*
- Volume 21 C. L. Young and P. G. T. Fogg, *Ammonia, Amines, Phosphine, Arsine, Stibine, Silane, Germane and Stannane in Organic Solvents*
- Volume 22 T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Halides in Nonaqueous Solvents*
- Volume 23 T. P. Dirkse, *Copper, Silver, Gold, and Zinc, Cadmium, Mercury Oxides and Hydroxides*
- Volume 24 W. Hayduk, *Propane, Butane and 2-Methylpropane*
- Volume 25 C. Hiraymana, Z. Galus and C. Guminski, *Metals in Mercury*
- Volume 26 M. R. Masson, H. D. Lutz and B. Engelen, *Sulfites, Selenites and Tellurites*
- Volume 27/28 H. L. Clever and C. L. Young, *Methane*
- Volume 29 H. L. Clever, *Mercury in Liquids, Compressed Gases, Molten Salts and Other Elements*
- Volume 30 H. Miyamoto and M. Salomon, *Alkali Metal Halates, Ammonium Iodate and Iodic Acid*
- Volume 31 J. Eysseľtová and T. P. Dirkse, *Alkali Metal Orthophosphates*
- Volume 32 P. G. T. Fogg and C. L. Young, *Hydrogen Sulfide, Deuterium Sulfide and Hydrogen Selenide*
- Volume 33 P. Franzosini, *Molten Alkali Metal Alkanoates*
- Volume 34 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part I: Non-cyclic Substituents*
- Volume 35 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part II: 5-Membered Heterocyclic Substituents*
