IUPAC Solubility Data Series Rates for 1995

Subscriptions:	UK and Europe	Rest of World
Full subscription	£265	\$395
Single volume	£80	\$120

Reduced rates are available to members of IUPAC. Please apply directly to the publisher for details.

Prices include postage by surface mail or, for subscribers in the USA and Canada by Airfreight or in Japan, India, Australia and New Zealand by Air Speeded Post. Airmail rates are available on request.

The IUPAC Solubility Data Series (ISSN 0191-5622) is published quarterly in March, June, September and December by Oxford University Press, Oxford, UK. Annual subscription price is US\$395. The IUPAC Solubility Data Series is distributed by Virgin Mailing & Distribution, 10 Camptown Road, Irvington, New Jersey 07111-1105, USA. Second Class postage paid at Newark, New Jersey, USA and additional entry points.

US POSTMASTER: send address corrections to IUPAC Solubility Data Series, c/o Virgin Mailing & Distribution, 10 Camptown Road, Irvington, New Jersey 07111-1105, USA.

New subscriptions may be registered at any time during the year but will be reckoned as running from January 1st of the year in which the subscription is received. Claims regarding non-receipt of issues must be received within 4 months of publication or date of order, whichever is later. Back issues are available—for information contact Journals Customer Services Department, Oxford University Press, Walton Street, Oxford OX2 6DP.

Order Information

Payment is required with all orders and may be made by the following methods:

Cheque (made payable to Oxford University Press)

National Girobank (Account 500 1056)

Credit Card (Access, Visa, American Express, Diners Club)

Direct Debit: Please send for further details

UNESCO Coupons

Bankers: Barclays Bank plc, PO Box 333, Oxford

Code 20-65-18. Account 00715654

Please send orders to: Journals Subscription Department, Oxford University Press, Walton Street, Oxford OX2 6DP. Tel: +44(0)1865 56767, Fax: +44(0)1865 267773

Any enquires regarding this publication should be addressed to:

INTRODUCTION TO THE SOLUBILITY DATA SERIES

SOLUBILITY OF LIQUIDS IN LIQUIDS

NATURE OF THE PROJECT

The Solubility Data project (SDP) has as its aim a comprehensive review of published data for solubilities of gases, liquids and solids in liquids or solids. Data of suitable precision are compiled for each publication on data sheets in a uniform format. The data for each system are evaluated and, where data from different sources agree sufficiently, recommended values are proposed. The evaluation sheets, recommended values, and compiled data sheets are published on consecutive pages.

This series is concerned primarily with liquid-liquid systems, but a limited number of related solid-liquid, fluid-fluid and multicomponent (organic-water-salt) systems are included where it is considered logical and appropriate. Solubilities at elevated and low temperatures and at elevated pressures have also been included, as it is considered inappropriate to establish artificial limits on the data presented if they are considered relevant or useful.

For some systems, the two components may be miscible in all proportions at certain temperatures and pressures. Data on reported miscibility gaps and upper and lower critical solution temperatures are included where appropriate and when available.

COMPILATIONS AND EVALUATIONS

The formats for the compilations and critical evaluations have been standardized for all volumes. A description of these formats follows.

Compilations

The format used for the compilations is, for the most part, self-explanatory. A compilation sheet is divided into boxes, with detailed contents described below.

Components: Each component is listed according to IUPAC name, formula, and Chemical Abstracts (CA) Registry Number. The Chemical Abstracts name is also included if this differs from the IUPAC name, as are trivial names if appropriate. IUPAC and common names are cross-referenced to Chemical Abstracts names in the System Index.

The formula is given either in terms of the IUPAC or Hill (1) system and the choice of formula is governed by what is usual for most current users: i.e., IUPAC for inorganic compounds, and Hill system for organic compounds. Components are ordered on a given compilation sheet according to:

- (a) saturating components:
- (b) non-saturating components in alphanumerical order;
- (c) solvents in alphanumerical order.

The saturating components are arranged in order according to the IUPAC 18-column periodic table with two additional rows:

Columns 1 and 2:	H, alkali elements, ammonium, alkaline earth elements
Columns 3 to 12:	transition elements
Columns 13 to 17:	boron, carbon, nitrogen groups; chalcogenides, halogens
Column 18:	noble gases
Row 1:	Ce to Lu
Row 2:	Th to the end of the known elements, in order of atomic number.

Organic compounds within each Hill formula are ordered in the following succession:

- (a) by degree of unsaturation
- (b) by order of increasing chain length in the parent hydrocarbon
- (c) by order of increasing chain length of hydrocarbon branches
- (d) numerically by position of unsaturation
- (e) numerically by position by substitution
- (f) alphabetically by IUPAC name.

Example:	
C ₅ H ₈	cyclopentane 2-methyl-1,3-butadiene 1,4-pentadiene 1-pentyne
C ₅ H ₁₀	cyclopentane 3-methyl-1-butene 2-methyl-2-butene 1-pentene 2-pentene
C ₅ H ₁₂	2,2-dimethylpropane 2-methylbutane pentane
C ₅ H ₁₂ O	2,2-dimethyl-1-propanol 2-methyl-1-butanol 2-methyl-2-butanol 3-methyl-1-butanol 3-methyl-2-butanol 1-pentanol 2-pentanol 3-pentanol
C ₆ H ₁₂ O	cyclohexanol 4-methyl-1-penten-3-ol 1-hexen-3-ol 4-hexen-3-ol

Deuterated (²H) compounds follow immediately the corresponding H compounds.

Original Measurements: References are abbreviated in the forms given by Chemical Abstracts Service Source Index (CASSI). Names originally in other than Roman alphabets are given as transliterated by Chemical Abstracts. In the case of multiple entries (for example, translations) an asterisk indicates the publication used for compilation of the data.

Variables: Ranges of temperature, pressure, etc. are indicated here.

Prepared by: The names of all compilers are given here.

Experimental Values: Components are described as (1), (2), etc., as defined in the "Components" box. Data are reported in the units used in the original publication, with the exception that modern names for units and quantities are used; e.g., mass per cent for weight per cent; mol dm³ for molar; etc. In most cases, both mass and molar values are given. Usually, only one type of value (e.g., mass per cent) is found in the original paper, and the compiler has added the other type of value (e.g., mole per cent) from computer calculations based on 1989 atomic weights (2). Temperatures are expressed as t/°C, t/°F or T/K as in the original; if necessary, conversions to T/K are made, sometimes in the compilations, and always in the critical evaluation. However, the author's units are expressed according to IUPAC recommendations (3) as far as possible.

Errors in calculations, fitting equations, etc. are noted, and where possible corrected. Material inserted by the compiler is identified by the word "compiler" or by the compiler's name in parentheses or in a footnote. In addition, compiler-calculated values of mole or mass fractions are included if the original data do not use these units. If densities are reported in the original paper, conversions from concentrations to mole fractions are included, but otherwise this is done in the evaluation, with the values and sources of the densities being quoted and referenced.

Details of smoothing equations (with limits) are included if they are present in the original publication and if the temperature or pressure ranges are wide enough to justify this procedure and if the compiler finds that the equations are consistent with the data.

The precision of the original data is preserved when derived quantities are calculated, if necessary by the inclusion of one additional significant figure. In some cases graphs have been included, either to illustrate presented data more clearly, or if this is the only information in the original. Full grids are not usually inserted as it is not intended that users should read data from the graphs.

Method: The apparatus and procedure are mentioned briefly. Abbreviations used in Chemical Abstracts are often used here to save space, reference being made to sources of further detail if these are cited in the original paper.

Source and Purity of Materials: For each component, referred to as (1), (2), etc., the

following information (in this order and in abbreviated form) is provided if available in the original paper: source and specified method of preparation; properties; degree of purity.

Estimated Error: If estimated errors were omitted by the original authors, and if relevant information is available, the compilers have attempted to estimate errors (identified by "compiler" or the compiler's name in parentheses or in a footnote) from the internal consistency of data and type of apparatus used. Methods used by the compilers for estimating and reporting errors are based on Ku and Eisenhart (4).

Comments and/or Additional Data: Many compilations include this section which provides short comments relevant to the general nature of the work or additional experimental and thermodynamic data which are judged by the compiler to be of value to the reader.

References: The format for these follows the format for the Original Measurements box, except that final page numbers are omitted. References (usually cited in the original paper) are given where relevant to interpretation of the compiled data, or where cross-reference can be made to other compilations.

Evaluations

The evaluator's task is to assess the reliability and quality of the data, to estimate errors where necessary, and to recommend "best" values. The evaluation takes the form of a summary in which all the data supplied by the compiler have been critically reviewed. There are only three boxes on a typical evaluation sheet, and these are described below.

Components: The format is the same as on the Compilation sheets.

Evaluator: The name and affiliation of the evaluator(s) and date up to which the literature was checked.

Critical Evaluation:

(a) Critical text. The evaluator checks that the compiled data are correct, assesses their reliability and quality, estimates errors where necessary, and recommends numerical values based on all the published data (including theses, reports and patents) for each given system. Thus, the evaluator reviews the merits or shortcomings of the various data. Only published data are considered. Documented rejection of some published data may occur at this stage, and the corresponding compilations may be removed.

The solubility of comparatively few systems is known with sufficient accuracy to enable a set of recommended values to be presented. Although many systems have been studied by at least two workers, the range of temperatures is often sufficiently different to make meaningful comparison impossible.

Occasionally, it is not clear why two-groups of workers obtained very different but internally consistent sets of results at the same temperature, although both sets of results were obtained by reliable methods. In such cases, a definitive assessment may not be possible. In some cases, two or more sets of data have been classified as tentative even though the sets are mutually inconsistent.

(b) Fitting equations. If the use of a smoothing equation is justifiable the evaluator may provide an equation representing the solubility as a function of the variables reported on all the compilation sheets, stating the limits within which it should be used.

(c) Graphical summary. In addition to (b) above, graphical summaries are often given.

(d) Recommended values. Data are recommended if the results of at least two independent groups are available and they are in good agreement, and if the evaluator has no doubt as to the adequacy and reliability of the applied experimental and computational procedures. Data are reported as tentative if only one set of measurements is available, or if the evaluator considers some aspect of the computational or experimental method as mildly undesirable but estimates that it should cause only minor errors. Data are considered as doubtful if the evaluator considers some aspect of the computational or experimental method as undesirable but still considers the data to have some value where the order of magnitude of the solubility is needed. Data determined by an inadequate method or under ill-defined conditions are rejected. However, references to these data are included in the evaluation together with a comment by the evaluator as to the reason for their rejection.

(e) References. All pertinent references are given here, including all those publications appearing in the accompanying compilation sheets and those which, by virtue of their poor precision, have been rejected and not compiled.

(f) Units. While the original data may be reported in the units used by the investigators, the final recommended values are reported in SI units (3) when the data can be converted accurately.

QUANTITIES AND UNITS USED IN COMPILATION AND EVALUATION OF SOLUBILITY DATA

Mixtures, Solutions and Solubilities

A *mixture* (5, 6) describes a gaseous, liquid or solid phase containing more than one substance, where the substances are all treated in the same way.

A *solution* (5, 6) describes a liquid or solid phase containing more than one substance, when for convenience one of the substances, which is called the *solvent*, and may itself be a mixture, is treated differently than the other substances, which are called *solutes*. If the sum of the mole fractions of the solutes is small compared to unity, the solution is called a *dilute solution*.

The *solubility* of a solute 1 (solid, liquid or gas) is the analytical composition of a saturated solution, expressed in terms of the proportion of the designated solute in a designated solvent (7).

"Saturated" implies equilibrium with respect to the processes of dissolution and demixing; the equilibrium may be stable or metastable. The solubility of a substance in metastable equilibrium is usually greater than that of the same substance in stable equilibrium. (Strictly speaking, it is the activity of the substance in metastable equilibrium that is greater.) Care must be taken to distinguish true metastability from supersaturation, where equilibrium does not exist.

Either point of view, mixture or solution, may be taken in describing solubility. The two points of view find their expression in the reference states used for definition of activities, activity coefficients and osmotic coefficients. Note that the composition of a saturated mixture (or solution) can be described in terms of any suitable set of thermodynamic components.

Physicochemical Quantities and Units

Solubilities of solids have been the subject of research for a long time, and have been expressed in a great many ways, as described below. In each case, specification of the temperature and either partial or total pressure of the saturating gaseous component is necessary. The nomenclature and units follow, where possible, ref. (3)

A note on nomenclature. The nomenclature of the IUPAC Green Book (3) calls the solute component B and the solvent component A. In compilations and evaluations, the first-named component (component 1) is the solute, and the second (component 2 for a two-component system) is the solvent. The reader should bear these distinctions in nomenclature in mind when comparing equations given here with those in the Green Book.

1. *Mole fraction* of substance 1, x_1 or $x(1)$:

$$x_1 = n_1 / \sum_{s=1}^c n_s \quad [1]$$

where n_s is the amount of substance of s , and c is the number of distinct substances present (often the number of thermodynamic components in the system). *Mole per cent* of substance 1 is $100 x_1$.

2. *Ionic mole fractions* of salt i , x_{i+} , x_{i-} :

For a mixture of s binary salts i , each of which ionizes completely into ν_{s+} cations and ν_{s-} anions, with $\nu_s = \nu_{s+} + \nu_{s-}$, and a mixture of p non-electrolytes j , of which some may be solvent components, a generalization of the definition in (8) gives:

$$x_{i+} = \frac{\nu_{i+} x_i}{1 + \sum_{i=1}^s (\nu_i - 1) x_i}, \quad x_{i-} = \frac{\nu_{i-} x_i}{\nu_{i+}} \quad i = 1 \dots s \quad [2]$$

$$x'_j = \frac{x_j}{1 + \sum_{i=1}^s (\nu_i - 1) x_i}, \quad j = (s+1), \dots, p \quad [3]$$

The sum of these mole fractions is unity, so that, with $c = s + p$,

$$\sum_{i=1}^s (x_{i+} + x_{i-}) + \sum_{i=s+1}^c x_i' = 1 \quad [4]$$

General conversions to other units in multicomponent systems are complicated. For a three-component system containing non-electrolyte 1, electrolyte 2 and solvent 3,

$$x_1 = \frac{v_{2+} x_1'}{v_{2+} - (v_2 - 1) x_{2+}} \quad x_2 = \frac{x_{2+}}{v_{2+} - (v_2 - 1) x_{2+}} \quad [5]$$

These relations are used in solubility equations for salts, and for tabulation of salt effects on solubilities of gases (see below).

3. *Mass fraction* of substance 1, w_1 or $w(1)$:

$$w_1 = g_1 / \sum_{s=1}^c g_s \quad [6]$$

where g_s is the mass of substance s . *Mass per cent* of substance 1 is $100 w_1$. The equivalent terms *weight fraction*, *weight per cent* and *g (1)/100 g solution* are no longer used.

4. *Molality* of solute 1 in a solvent 2, m_1 :

$$m_1 = n_1 / n_2 M_2 \quad [7]$$

SI base units: mol kg⁻¹. Here, M_2 is the molar mass of the solvent.

5. *Aquamolality*, *Solvomolality* of substance 1 in a mixed solvent with components 2, 3 (9), $m_1^{(3)}$:

$$m_1^{(3)} = m_1 \bar{M} / M_3 \quad [8]$$

SI base units: mol kg⁻¹. Here, the average molar mass of the solvent is

$$\bar{M} = x_2' M_2 + (1 - x_2') M_3 \quad [9]$$

and x_2' is the solvent mole fraction of component 2. This term is used most frequently in discussing comparative solubilities in water (component 2) and heavy water (component 3) and in their mixtures.

6. *Amount concentration* of solute 1 in a solution of volume V , c_1 :

$$c_1 = [\text{formula of solute}] = n_1 / V \quad [10]$$

SI base units: mol m⁻³. The symbol c_1 is preferred to [formula of solute], but both are used. The old terms *molarity*, *molar* and *moles per unit volume* are no longer used.

7. *Mass concentration* of solute 1 in a solution of volume V , ρ_1 : SI base units: kg m⁻³.

$$\rho_1 = g_1 / V \quad [11]$$

8. *Mole ratio*, $r_{n,12}$ (dimensionless)

$$r_{n,12} = n_1 / n_2 \quad [12]$$

Mass ratio, symbol $r_{g,12}$, may be defined analogously.

Mole and mass fractions are appropriate to either the mixture or the solution point of view. The other quantities are appropriate to the solution point of view only. Conversions between pairs of these quantities can be carried out using the equations given in Table 1 at the end of this Introduction. Other useful quantities will be defined in the prefaces to individual volumes or on specific data sheets.

9. Density, ρ :

$$\rho = g/V \quad [13]$$

SI base units: kg m^{-3} . Here g is the total mass of the system.

10. *Relative density*, $d = \rho/\rho^\circ$: the ratio of the density of a mixture at temperature t , pressure p to the density of a reference substance at temperature t' , pressure p' . For liquid solutions, the reference substance is often water at 4°C , 1 bar. (In some cases 1 atm is used instead of 1 bar.) The term *specific gravity* is no longer used.

Thermodynamics of Solubility

Thermodynamic analysis of solubility phenomena provides a rational basis for the construction of functions to represent solubility data, and thus aids in evaluation, and sometimes enables thermodynamic quantities to be extracted. Both these are often difficult to achieve because of a lack of experimental or theoretical activity coefficients. Where thermodynamic quantities can be found, they are not evaluated critically, since this task would involve examination of a large body of data that is not directly relevant to solubility. Where possible, procedures for evaluation are based on established thermodynamic methods. Specific procedures used in a particular volume will be described in the Preface to that volume.

ρ - density of solution; M_i - molar masses of *i*. For relations for 2-component systems, set summations to 0.

PREFACE

This volume contains a comprehensive collection and critical evaluation of solubility data published prior to 1993 for halogenated methanes with water, seawater, heavy water, and aqueous electrolyte solutions. The systems are ordered on the basis of chemical formula according to the Hill system.

A critical evaluation of the solubility data is not satisfactory without a comprehensive literature search followed by compilation of all the available information reported in journals, patents, pamphlets, brochures, books, etc. The difficulties and problems in retrieval of all solubility data are a well recognized fact. Some of the difficulties which arose during the retrieval of the original publications for this volume were:

- i. The articles, reports, etc. were not cited in the Chemical Abstracts
- ii. The British Library did not hold the publications
- iii. The Slavonic Section of the British Library was unable to obtain some publications from abroad
- iv. Manufacturers' reports, leaflets, brochures, etc. were not available from industrial source
- v. University reports from experimental stations were not available from university libraries.

In summary, there were several cases where the original sources were not obtainable and the information had to be taken from secondary sources.

The referenced literature sources can be classified into the following groups:

- A. Bibliographies
- B. Secondary sources (books, reviews)
- C. Databases (computer softwares)
- D. Primary sources (journals, reports, etc.)

A list of the various sources of solubility data following the above classification is summarized in Table 1.

Table 1. Sources of Solubility Data

A. Bibliographies:

1. Wisniak, J.; Tamir, A. *Liquid-Liquid Equilibrium and Extraction. A Literature Source Book*, Elsevier, Amsterdam, 1980, 1252 pp.
2. Wisniak, J.; Herskowitz, M. *Solubility of Gases and Solids. A Literature Source Book*, Parts A and B, Elsevier, Amsterdam, 1984, 2070 pp.

B. Secondary Sources:

3. Brochures, leaflets
4. Patents
5. Private communications

Once a copy of the original document - usually a photocopy - was obtained, the first step was to read it carefully. Often the original article was in a foreign language which required a translation. If the description was not focused on the solubility aspect, then often some relevant details, e.g., source and purity of the solute and solvent, or both, were not included in the text. In many cases, the method, apparatus, and procedure were simply referred to other articles. Furthermore, when the experimental errors were not stated, the compiler sometimes introduced a subjective judgement for the accuracy of the measured solubility and temperature. The estimated accuracy of the measured quantities is quite subjective and the readers must take this fact into consideration.

The summaries of the procedures and abstracts were based on the available description of the method, apparatus, and procedures. Often a short statement "Details are not available," had to be used when the main contents of the articles focused not on solubility measurements but some other aspects of chemistry.

The conversion of the published solubility data into conventional units often presented difficulties, particularly when the dimensions were not expressed clearly. For example, the Henry's law constants, separation coefficients, distribution ratio, partition coefficients, etc. were not specified explicitly. Some of the more relevant conversion formulas are given in Table 2.

To convert solubility data from one unit to another, often the density and vapor pressure of the pure components and/or of the mixture were needed. The physical properties of the pure compounds were taken from the DIPPR (ref. 1) and TRCVP (ref. 2) databases. To find or derive the physical properties of mixtures required a more elaborate effort. Experimental data, e.g., density and vapor pressure for aqueous solutions of halogenated hydrocarbons are extremely rare in the literature. Consequently, approximations were obtained using calculations recommended in standard handbooks, e.g., Reid et al. (ref. 2). An illustration of the

Table 2. Conversion Formulas for Solubility Units.

a. Henry's Law Constant (H):

$$\text{Mass } \% = \frac{\left[\frac{P_{\text{vap}} (\text{atm}) M_{\text{solute}}}{H (\text{dimensionless})} \right]}{82.06 T (\text{K}) d_{\text{solvent}} (\text{g cm}^{-3})} \times 100$$

$$\text{Mass } \% = \frac{\left[\frac{P_{\text{vap}} (\text{atm}) M_{\text{solute}}}{H (\text{m}^3 \text{atm mol}^{-1})} \right]}{d_{\text{solvent}} (\text{g cm}^{-3})} \times 10^{-4}$$

$$H (\text{dimensionless}) = \frac{C_{\text{air}}}{C_{\text{solvent}}} = \frac{16.04 P_{\text{vap}} (\text{mmHg}) M_{\text{solute}}}{T (\text{K}) S_{\text{solute}} (\text{mg / dm}^3)}$$

b. Air/Water Partition Coefficient (K_{AW}):

$$\text{Mass } \% = \frac{100 K_{AW} P_{\text{vap}}}{82.054 T (\text{K}) d_{\text{solvent}}}$$

c. Distribution Ratio (p/c):

$$(p/c) = \frac{\text{solute vapor pressure}}{\text{solute concentration}} = \frac{(\text{mmHg})}{(\text{mmole/ dm}^3)}$$

d. Partition Coefficient (K):

$$K = \frac{1}{\text{Ostwald coefficient}} = \frac{1}{L}$$

e. Distribution Coefficient (K_d):

$$K_d = \text{Ostwald coefficient} = L = \frac{y_i}{x_i}$$

difficulty of obtaining accurate conversions is shown by the following typical case.

The solubility of carbon tetrachloride (CCl_4) in water (H_2O) is $0.10 \text{ cm}^3/100 \text{ cm}^3$ water at 25°C . The solubility in mass per cent ($100 w_1$) is required. The density of pure carbon tetrachloride is $1.5834 \text{ g CCl}_4/\text{cm}^3$ at 25°C (DIPPR database). The solution density is required to convert the pure water density using the mass of the aqueous solution of carbon tetrachloride at 25°C . However, the density of the aqueous solution of carbon tetrachloride has not been reported in the literature. The reason is quite simple; the difference between the density of pure water and that of the aqueous solution of carbon tetrachloride at 25°C is marginal. As a consequence, the errors obtained upon the determination of solubility are considerably greater than the possible difference between the solubility in pure water or in its aqueous solutions at the same temperature. It follows, in this case, one must use the approximation

$$\text{g CCl}_4 / 100 \text{ g H}_2\text{O} \approx 100 w_1 .$$

On the other hand, for solubility values larger than, say, 2 - 3 mass per cent, the differences become significant, as the following example illustrates. The solubility in water of dichloromethane (CH_2Cl_2) is $2.363 \text{ g}/100 \text{ g}$ water at 0°C . The mass per cent solubility, $100 w_1$, at the same temperature is required.

If 100 g water dissolves 2.363 g CH_2Cl_2 , then the total mass of the solution becomes 102.363 g. This means that 100 g aqueous solution will dissolve less CH_2Cl_2 than 100 g pure water, that is,

$$100 w_1 = \frac{2.363 \text{ g } \text{CH}_2\text{Cl}_2}{102.363 \text{ g soln.}} 100 = 2.3084 .$$

The resulting mass per cent is 2.3084 at 0°C. Consequently, there is a 2.31 per cent reduction in the solubility relative to 100 g pure water. This is in comparison to the reduction of only 0.10 per cent in the case of the solubility of CCl_4 in 100 g water or 100 g aqueous solution at 25°C.

All critical evaluations of the solubility data are presented on the evaluation sheets. The information available on the relevant compilation sheets served as the fundamental source for the critical evaluations. The following main aspects of the solubility data have been considered:

- Purity of the components (solute and solvents)
- Date of the experiment
- Accuracy of the method
- Reproducibility of the experiment
- Experience of the investigator(s), previous publications
- Consistency of the data, trends in series

Once these aspects of the works had been examined, efforts were made to weight the reliability of the reported data. As much as possible, the differences in the quality of the data have been taken into account.

The available solubility data for binary systems may be very scarce, medial, or abundant, depending on the commercial application of the systems. Whenever data from different sources exist, they often disagree. For evaluation of the agreement or disagreement among the data, graphical presentations usually provide the clearest picture. The figures normally contain the original data from all references for a given system. A plot representing the solubility data (expressed in mole fraction or mass per cent) can reveal whether or not a trend exists among the data in addition to highlighting any discrepancies of the experimental solubility measurements.

The final data can be classified as:

- obscure or dubious - rejected data
- tentative - not recommended data
- recommended - good agreement among the published results.

A graphical presentation of the solubility data may be performed on linear, semi-logarithmic, etc. scales. The unit of solubility may be given as specific or molar scales. For practical reasons, the mass per cent unit is often used, whereas the mole fraction is another common unit of solubility. In this volume most figures are plotted using one of two different scales. For the solubilities in water, linear graphs are used and for the solubilities of water in halogenated hydrocarbons, the so called Cox chart is applied. In the Cox charts, the solubility of water is given as $\log_{10} x_2$ versus $1/T$. A straight line on a Cox plot can be very useful for revealing consistent data covering a limited temperature range. However, the straight line does not apply for solubility data over a very wide temperature interval, e.g., from the triple point to the critical point. Therefore, in some cases (e.g., solubility of water in chloroform), the normal polynomial equations were used for smoothing the solubility data.

To fit experimental data into the various equations, the individual data points are often weighted. The smoothed data may be influenced somewhat by such procedures of weighting individual data points. Data analysis is a process of mathematical and/or graphical treatment of experimental data through the use of statistical or parametric procedures. Whenever the raw data are fragmentary, the aim is to generate an extended range of internally consistent values by synthesis. In any case, the temperature dependence of solubility must be examined and any unusual irregularities must be investigated carefully.

The temperature dependence of the solubility of halogenated hydrocarbons in water has been correlated using normal polynomial equations over limited temperature intervals. These equations should be used only in the temperature range indicated. The equations play two major roles; to provide data users with interpolated data with good accuracy and to provide data users with acceptable data for use in computer programs, if desired. The deviation of the various experimental values from the fitted data are given as standard or average deviations.

If the experimental data cover a reasonable temperature interval, then the data and the smoothing equation are often illustrated in a figure. The graphical presentation of the reported and fitted data clearly indicates the risks involved when one attempts to extrapolate the raw experimental data. In some cases, an extrapolation is quite safe for the desired temperature (see for example, the solubility of water in halogenated hydrocarbons over moderate temperature intervals); whereas, in other cases, the risk is very high and it is not recommended. The shape of the solubility curves suggests the extrapolation and interpolation possibilities.

Whether the mutual solubility between two liquids is partial or complete depends on the similarities or differences between the molecules of the two chemical compounds. The halogenated hydrocarbon and water systems are only partially miscible without exception. Furthermore, the miscibility or immiscibility of water with other liquids is also very dependent upon temperature. At ambient temperature and atmospheric pressure, the miscibility is very limited between water and halogenated hydrocarbons. For most systems, the mutual solubility is less than 2 mass per cent at ambient room temperatures.

In a liquid-liquid system the variation of solubility with temperature depends on the sign of the heat of mixing or solution. The minimum dissolution temperature occurs for most halogenated hydrocarbon - water systems between 270 and 310 K. The interactions between the solute and solvent molecules provide the explanation for the phenomena. The temperature dependence of solubility is a result of temperature dependent structural modifications of water. A different energy is required for cavity formation and for the changes in rigidity of the lattice as temperature is changed.

The appearance of these minima resembles the dependence of the critical micelle concentration upon temperature. Here, the iceberg formation of water molecules around the monodisperse solute enhances the critical micelle concentration, the logarithm of which would be decreased linearly with $1/T$ provided the solution behaves regularly, and the iceberg formation increases with a temperature reduction.

It is well recognised that the rare gases and hydrocarbon gases form iceberg-like structures when dissolved in cold water, followed by an iceberg melting as the temperature is raised. The solubility of most gases in water shows a minimum when plotted against temperature. The shape of the solubility curves for molecules with alkyl groups is explained by considering that the ice-like structure of water is also formed around the nonpolar alkyl group of molecules in water. This structure tends to break down as the temperature of the solution is increased.

The minimum solubility temperature can be calculated from a calorimetric measurement of the enthalpy of solution at infinite dilution ($\Delta_{soln}H^\infty$). This value is very large and varies from negative to positive values within a small temperature range. Consequently, very large errors may be caused by an erroneous interpretation. In addition to the enthalpy of solution, the change in the heat capacity at infinite dilute aqueous solution ($\Delta_{soln}C_p^\infty$) is required for the calculation of the minimum solubility temperature (T_{min}):

$$T_{min} = 298.15 \text{ K} - \frac{\Delta_{soln}H^\infty(298.15 \text{ K})}{\Delta_{soln}C_p^\infty}$$

A more detailed description of the minimum solubility phenomenon is given by Horvath (ref. 4), Shinoda (ref. 5), Nishino and Nakamura (ref. 6), and Privalov and Gill (ref. 7).

The relations between the solubility and some of the physical properties of the solute or solvent have been investigated from early times in solution studies. The various experiments showed that in very diluted solutions the influence of the solute molecules does not extend to all solvent molecules in the solution. Consequently, the large fraction of solvent molecules, which are not affected by solute molecules, must exist more or less in the same state of aggregation as in the pure state. A change of solvent molar volume in dilute solutions is very small. However, in more concentrated solutions the effects of the presence of the solute molecules on the solvent molecules are not negligible. The amount of molar volume change of the solvent depends on the nature of the solutes. The dissolution process is related to the disintegration of the solute in the solvent, as compared to its pure state molecular order, as a result of the mutual action of attraction of the solute and solvent.

In general, solubility depends on many parameters and is of a very complex nature. There is no simple relation established between solubility and the other properties of the pure components (solute and solvent). Despite the lack of a simple relationship, the solubility of halogenated benzenes in water at 25°C has been correlated with a reasonable success using the molar volume of the solutes (ref. 8). Similarly, the solubility of halogenated methanes in water shows a linear relationship (ref. 9). The correlation is based on the assumption that the molar volumes in saturated solutions are not greatly different from those in the pure state. The simple linear relation at 25°C is illustrated graphically in Figure 1. This is a very useful and practical way to show the consistency of the solubility data. Any significant deviation from such a linear relationship suggests some inconsistency and introduces doubt concerning the reliability of the data.

Figure 1. Logarithm of Saturated Molarity versus Solute Molar Volume at 25 °C for Halogenated Methanes in Water.

Correlation equation:

$$\log_{10} (S / \text{mole dm}^{-3}) = 1.8995 - 4.3707 \times 10^{-2} (V_m / \text{cm}^3 \text{mole}^{-1})$$

--	---

CRITICAL EVALUATION:

The trichlorofluoromethane (1) and water (2) binary system is discussed in two parts; part 1 is trichlorofluoromethane (1) in water (2) and part 2 is water (2) in trichlorofluoromethane (1).

Part 1. The solubility of trichlorofluoromethane (1) in water (2) has been studied by at least eleven different work groups with only partial agreement of results. The data of Howe *et al.* (ref. 1) are substantially lower than other measurements and are therefore rejected. The solubility data reported by du Pont (refs. 2 and 3), Rauws *et al.* (ref. 4), McConnell *et al.* (ref. 5), Pearson and McConnell (ref. 6), and Sukornick (ref. 7) show some consistency, while the measurements reported by Park *et al.* (ref. 8), Warner and Weiss (ref. 9), Wisegarver and Cline (ref. 10), Warner *et al.* (ref. 11), Balls (ref. 14), and Zeininger (ref. 15) are relatively high in value.

It may be assumed that the solubility data reported in the du Pont bulletins were produced in the same laboratories with similar methods and accuracy at 298.15 and 304.15 K, respectively. There appears to be no significant difference between the two data points despite the 6 K difference in temperature. Similarly, the two measurements reported by McConnell *et al.* and Pearson and McConnell in 1975 most likely were made in the same laboratories under much the same conditions.

There is no obvious reason to explain the difference between the lower (refs. 2, 3, 5, 6, and 7) and higher (refs. 8, 9, 10, 11, 14, and 15) sets of data. In the opinion of the evaluator, there is not enough evidence to justify rejection of measurements from either of the two data sets. Although both data sets are classified as tentative, the smoothed solubility values in mass per cent (1) for the 273 through 313 K temperature interval (Table 1) are based upon a regression equation for all data shown in Figure 1:

$$\text{Solubility [100 } w_1] = 25.0094 - 0.16263 (T/K) + 2.6547 \times 10^{-4} (T/K)^2$$

with a standard error of 5.0×10^{-2} about the regression line.

A minimum solubility occurs for most halogenated hydrocarbons in water systems between 270 and 310 K (refs. 12 and 13). A minimum solubility temperature can be calculated from an enthalpy of solution at infinite dilution and a change in solute heat capacity in going from a pure liquid to an infinitely dilute aqueous solution. However, such thermodynamic data are rarely available in the literature.

Part 2. The solubility of water (2) in trichlorofluoromethane (1) has been measured by three research groups (refs. 2, 3, and 7) with only partially consistent results with the exception of the measurements of Sukornick (ref. 7). Generally, the solubility behavior of water in halogenated hydrocarbons shows a definite increase with increasing temperature. This trend has been demonstrated in a comprehensive compilation of solubility data (ref. 12). The two measurements at 294.15 and 298.15 K from the du Pont laboratories compare favorably with the recommended values, whereas the reported value of Sukornick (ref. 7) at 304.15 K is low and classified as doubtful. More accurate solubility measurements are required for more reliable values.

AUXILIARY INFORMATION																					
METHOD/APPARATUS/PROCEDURE: <p>The method involved repeated equilibrations of nitrogen with a liquid water sample containing the trichlorofluoromethane. Each sample was shaken vigorously at the required temperature in a constant temperature bath for 30 minutes. The equilibrated gas phase was then injected into a gas chromatograph. The experiments were performed at least three times at 10, 15, 20, and 25 °C; each experiment involved about six equilibrations.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled. ESTIMATED ERRORS: Solubility: See above. Temperature: ± 0.5 K (compiler).

AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: <p>The original method and apparatus for the determination of Henry's law constants are described in Mackay <i>et al.</i> (ref. 1). The general procedure was to add an excess of the organic compound to distilled deionized water and stir the mixture overnight. A portion of this solution was returned to a stripping vessel. The solute was stripped isothermally from the solution at a known gas flow rate. The Henry's law constant was calculated from a log of the concentration versus time plot. The experimental data points are averages of two or more replicates.</p>	SOURCE AND PURITY OF MATERIALS: (1) Purest quality available and used without further purification; stated purity > 99 %. (2) Distilled deionized. ESTIMATED ERRORS: Solubility: ± 6 % std. dev. Temperature: ± 0.05 K. REFERENCES: (1) Mackay, D.; Shiu, W. Y.; Sutherland, R. D. <i>Environ. Sci. AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: <p>250 ml bottles were filled with distilled deionized water and sealed. Measured volumes of trichlorofluoromethane were injected into the bottles through each bottle septum using a microliter syringe. The solute was in excess of the anticipated solubility limit. The bottles were shaken for 1 hour with a wrist-action shaker and allowed to equilibrate for about 3 weeks. Samples were then injected into a gas chromatograph equipped with a Carbo-pack column and a FID detector. The GC responses were compared with a calibration plot to establish concentrations.</p>	SOURCE AND PURITY OF MATERIALS: (1) Probably a commercial reagent, at least 99 % purity, used as received. (2) Distilled deionized. ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 0.5 K (compiler).

AUXILIARY INFORMATION																					
METHOD/APPARATUS/PROCEDURE: Degassed liquid trichlorofluoromethane samples were introduced into degassed seawater samples up to saturation at which point two phases appeared. After shaking a sample for several hours equilibrium was achieved and the respective phases were analysed with a gas liquid chromatograph. The original report is not obtainable; therefore, the details were taken from Junge (ref. 1).	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) North Atlantic surface water, salinity not given. ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 1 K (compiler). REFERENCES: (1) Junge, C. <i>Z. METHOD/APPARATUS/PROCEDURE: The method involved repeated equilibrations of nitrogen with a water sample containing trichlorofluoromethane. The sample was shaken vigorously at the required temperature in a constant temperature bath for 30 minutes. The equilibrated gas phase was then injected into a gas chromatograph. The experiments were performed at least three times at 10, 15, 20, and 25 °C with each experiment involving about six equilibrations.		SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Salinity = 20 ‰.		
		ESTIMATED ERRORS: Solubility: See above. Temperature: ± 0.5 K (compiler).

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The equilibration occurred in a 2 liter flask rotating in a constant temperature water bath for 20 hours. The analysis of CCl ₃ F was carried out using a Hewlett-Packard ⁶³ Ni electron capture detector mounted in a gas chromatograph. Peak areas were quantified by a HP 3388A integrator and compared to the detector response of a standard sample.		SOURCE AND PURITY OF MATERIALS: (1) AIRCO, Inc., used as received. AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE: Equilibration of a dilute mixture of trichlorofluoromethane gas with seawater occurred in an equilibration chamber at various temperatures. Both gas and liquid phase concentrations were measured by gas chromatography using a Shimadzu ⁶³ Ni electron capture detector operating in a constant current mode.	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Surface water collected at La Jolla. Salinity = 35.807 ± 0.006 × 10 ⁻³ . ESTIMATED ERRORS: Solubility: ± 1.5 %. Temperature: ± 0.02 K.

COMPONENTS: (1) Tetrachloromethane (carbon tetrachloride); CCl ₄ ; [56-23-5] (2) Water; H ₂ O; [7732-18-5]	EVALUATOR: A. L. Horvath, Imperial Chemical Industries Limited, Runcorn, U.K. January 1993.
--	---

CRITICAL EVALUATION:

The tetrachloromethane (1) and water (2) binary system is discussed in two parts; part 1 is tetrachloromethane (1) in water (2) and part 2 is water (2) in tetrachloromethane (1).

Part 1. The solubility of tetrachloromethane (1) in water (2) has been studied by 41 workers. The experimental data of most investigators in the 273 to 303 K temperature interval are sufficiently reliable to use in a smoothing equation. Even though a number of measurements above 308 K were reported, the solubility values in this temperature range are rather uncertain and are classified as doubtful.

The experimental work of several workers was not used for the smoothing equation for a variety of reasons. The measured solubility of Booth and Everson (refs. 1 and 2) and of Karger *et al.* (ref. 3) are markedly higher than the solubility values calculated from the smoothing equation. The measurements by Powell (ref. 4), Tettamanti *et al.* (ref. 5), Svetlanov *et al.* (ref. 6), Antropov *et al.* (ref. 7), Simonov *et al.* (ref. 8), Sato and Nakijima (ref. 9), Coca *et al.* (ref. 10), Balls (ref. 11), Yoshioka *et al.* (ref. 12), Howe *et al.* (ref. 13), and Wright *et al.* (ref. 14) are all several per cents lower than the smoothed solubility values and have also been rejected. The solubilities calculated from the distribution coefficients of Prosyantov *et al.* (ref. 15) are in very poor agreement, giving little confidence in their values which were regarded as dubious.

The remaining data from 26 laboratories were compiled or used for the smoothing equation. The data are also shown in Figure 1. The fitting equation obtained for mass per cent (1) is given by:

$$\text{Solubility [100 } w_1] = 3.4653 - 0.0230285 (T/K) + 3.91621 \times 10^{-5} (T/K)^2$$

The equation represents the combined data points which yield a standard deviation of 5.8×10^{-3} in the 273 to 308 K temperature range.

The curve obtained from the smoothing equation shows a distinct minimum at 294 K, as seen in Figure 1. The existence of the minimum solubility is discussed in the Preface.

The recommended solubility values at 5 K intervals for tetrachloromethane (1) in water (2) are presented in Table 1.

Table 1. Tentative Solubility of Tetrachloromethane (1) in Water (2)

Temperature		Solubility	
°C	K	100 w_1	$10^4 x_1$
0	273.15	0.0970	1.137
5	278.15	0.0898	1.053
10	283.15	0.0846	0.9916
15	288.15	0.0813	0.9529
20	293.15	0.0800	0.9376
25	298.15	0.0813	0.9529
30	303.15	0.0832	0.9752
35	308.15	0.0878	1.029

COMPONENTS: (1) Tetrachloromethane (carbon tetrachloride); CCl_4 ; [56-23-5] (2) Water; H_2O ; [7732-18-5]	EVALUATOR: A. L. Horvath, Imperial Chemical Industries Limited, Runcorn, U.K. January 1993.
---	---

CRITICAL EVALUATION: (continued)

Figure 1. Solubility of Tetrachloromethane (1) in Water (2).

Part 2. The solubility of water (2) in tetrachloromethane (1) has been reported by 37 laboratories since 1921. The solubility measurements cover the 273 to 373 K temperature range, see Figure 2. However, the data available above 323 K originate from only two investigators (refs. 16 and 17). The recommended solubility values are limited to the 283 to 307 K temperature interval.

Although data from all the workers show a general increase in solubility with temperature, the extent of the increase is variable above 313 K.

The data of Bell (ref. 18), Niini (ref. 19), and Fox and Martin (ref. 20) are substantially lower than all other studies and they have been rejected. The data of Eberius (ref. 21), Zielinski (ref. 22), Grigsby (ref. 23), Goldman (ref. 24), Ohtsuka and Kazama (ref. 25), and Kleeberg *et al.* (ref. 26) are significantly higher than the likely solubility and were also rejected. The remaining data mainly due to Clifford (ref. 27), Rosenbaum and Walton (ref. 28), Staverman (ref. 29), Hutchison and Lyon (ref. 30), McGovern (ref. 31), Donahue and Bartell (ref. 32), Rotariu *et al.* (ref. 33), Greinacher *et al.* (ref. 34), Desnoyer (ref. 35), Tettamanti *et al.* (ref. 5), Johnson *et al.* (refs. 36 and 37), Johnson (ref. 38), Christian *et al.* (ref. 39), Högfeldt and Fredlund (ref. 41), Simonov *et al.* (refs. 8, 41 and 42), Glasoe and Schultz (ref. 43), Antropov *et al.* (ref. 7), Kirchnerova (ref. 44), Kirchnerova and Cave (ref. 45), Coca *et al.* (ref. 10), Ksiazczak and Buchowski (ref. 46), Wu (ref. 17), and Orlandini *et al.* (ref. 47) are in good agreement, especially the values given in (refs. 31, 43, and 17).

The correlating equation for the combined mass per cent solubilities of water in tetrachloromethane between 283 and 308 K is as follows:

$$\text{Solubility [100 } w_2] = 0.301104 - 2.348078 \times 10^{-3} (T/K) + 4.607143 \times 10^{-6} (T/K)^2$$

This equation yielded a standard deviation of 1.5×10^{-3} in the 273 to 308 K temperature range.

METHOD/APPARATUS/PROCEDURE: <p>An about 1 to 5 ratio of water/tetrachloromethane mixture was rotated in a thermostat for 12 hours. After the equilibrium was attained, samples were taken and filtered through cottonwool. The determination of the water content was based upon the reaction with α-naphthoxydichlorophosphine. The evolved HCl was absorbed in water and titrated with NaOH solution (ref. 1). Two to three successive determinations were carried out with the tetrachloromethane.</p>	SOURCE AND PURITY OF MATERIALS: (1) Distilled (compiler). METHOD/APPARATUS/PROCEDURE: Tetrachloromethane was shaken with water for about 12 hours in a liquid paraffin thermostat bath. The water content of the organic phase was determined by the Karl Fischer titration method. All measurements were done in duplicates. The results were averages of two measurements at each temperature. A full description of the method used is given in a Ph. D. thesis (ref. 1).		SOURCE AND PURITY OF MATERIALS: (1) Distilled. (2) Source and purity not given.	
		ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 0.5 K (compiled).

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: A 1 to 15 volume ratio mixture of water and tetrachloromethane was introduced into an equilibration flask and then lowered into a waterbath thermostat. The assembly was shaken mechanically for about 90 minutes at constant temperature. The amount of water in the organic phase was determined by a modified Karl Fischer titration. The determination was done in triplicate. This description of procedure was taken from a secondary source (ref. 1). The original university report is no longer available.		SOURCE AND PURITY OF MATERIALS: (1) Distilled. (2) Source is not known. Purified and dried before use.

METHOD/APPARATUS/PROCEDURE: A tetrachloromethane - air mixture was bubbled through 50 cm^3 distilled water contained in a gas absorption bottle with a sintered glass plate. Equilibrium was reached in 3/4 hour with a gas flow of $50 \text{ cm}^3/\text{min}$. The saturated solution was transferred to a measuring cylinder and shaken with toluene. The toluene extraction was allowed to settle and then analyzed for tetrachloromethane by the addition of pyridine and alkali; see (ref. 1). METHOD/APPARATUS/PROCEDURE: Gas-liquid chromatography was used for the determination of the partition of tetrachloromethane with thin layers of water coated on Porasil D. Helium carrier. The gas was presaturated with water at the column temperature. The eluents were detected with an F. & N. flame ionization detector. The partition coefficient (K_L) was obtained from the slope of the straight line plot of V_N/A_L vs. V_I/A_L .	SOURCE AND PURITY OF MATERIALS: (1) J. T. AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: Tetrachloromethane was equilibrated with an excess of water in a vessel under rotation in a water bath for 1 hour. Aliquots of the water saturated organic solvent were taken for analysis with calibrated Hamilton syringes. The analyses were performed with an Aquatest II automatic Karl Fischer titrator. During the analyses, the coulometer current generated by the instrument was checked with an accurate milliammeter.		SOURCE AND PURITY OF MATERIALS: (1) Distilled. (2) Source not given. Certified grade, dried with CaCl ₂ and distilled under dry nitrogen, density = 1.5826 g/cc at 25°C.		
		ESTIMATED ERRORS: Solubility: ± 0.18 std. dev. Temperature: ± 0.02 K.		
COMPONENTS: (1) Tetrachloromethane (carbon tetrachloride); CCl ₄ ; [56-23-5] (2) Water; H ₂ O; [7732-18-5]		ORIGINAL MEASUREMENTS: Simonov, V. D.; Shamsutdinov, T. M.; Pogulyai, V. E.; Popova, L. N. <i>Russ. J. Phys. Chem.</i> <u>1974</u> , 48, 1573-5.

AUXILIARY INFORMATION																																	
METHOD/APPARATUS/PROCEDURE: A 5 μL tetrachloromethane sample was injected into a 2.3 liter equilibration cell containing distilled water. After the cell was shaken vigorously for about 5 minutes, the homogeneity of the liquid sample was maintained with a magnetic stirrer. Compressed air was passed through the cell and the gas flow was measured with a soap film flowmeter. The tetrachloromethane content was extracted and analyzed using a dual flame ionization detector gas chromatograph.	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. METHOD/APPARATUS/PROCEDURE: <p>A modification of the EPICS procedure was used for measuring Henry's law constants. A precise quantity of tetrachloromethane was injected into serum bottles which contained distilled water. The bottles were incubated for 18 - 24 hours at four desired temperatures in a reciprocating shaker bath. The headspace concentrations of the EPICS bottles were measured by a gas chromatograph which was equipped with a flame ionization detector. The mean of the coefficient of variation values was approximately 4.3 %.</p>	SOURCE AND PURITY OF MATERIALS: (1) J. T. Baker reagent, analytical grade. Used as received. (2) Distilled. AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: <p>The original method and apparatus for the determination of Henry's law constant, as described by Mackay <i>et al.</i> (ref. 1), was used. The general procedure was to add an excess quantity of tetrachloromethane to distilled deionized water, place the sample in a thermostat bath, and provide overnight mixing. A portion of this solution was returned to the stripping vessel. Tetrachloromethane was stripped isothermally from the solution at a known gas flow rate. The Henry's law constant was calculated from the log of the concentration versus time plot. The experimental data values are averages of two or more replicates.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source not given. Purest quality available was used without further purification. METHOD/APPARATUS/PROCEDURE: <p>250 ml bottles were filled with distilled and deionized water and sealed. A measured volume of tetrachloromethane was injected into the bottles through each septum using a microliter syringe. Tetrachloromethane was in excess of the anticipated solubility limit. The bottles were shaken for one hour with a wristaction shaker and allowed to equilibrate for about 3 weeks. Samples were then injected into a gas chromatograph equipped with a Carbo-pack column and a FID detector. The GC response was compared with calibration plots.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source not given. Probably a commercial reagent, at least 99 % purity. Used as received. (2) Distilled and deionized. ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 0.5 K (compiler).

METHOD/APPARATUS/PROCEDURE: A differential static cell equilibrium apparatus was used to measure the infinite dilution activity coefficient of tetrachloromethane (γ^{∞}) in water. Cells containing degassed water were submerged in a thermostated water bath. Tetrachloromethane was injected into the mixture cells and a magnetic stirrer was turned on. The cells were allowed to equilibrate. The stirrer was then turned off and the differential pressure was recorded. The experiment was repeated at least three times at each temperature. AUXILIARY INFORMATION																													
METHOD/APPARATUS/PROCEDURE: <p>The multiple equilibrium technique was used to measure the Henry's law constant (H) as described by McAuliffe (ref. 1). A known volume of seawater in a syringe was shaken with a known volume of tetrachloromethane. After equilibration, the headspace was separated and analyzed for tetrachloromethane. A gas chromatograph with an electron capture detector was used for the analysis.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Samples from 48°N to 65°S in the Atlantic in late 1981.																												
ESTIMATED ERRORS: Solubility: ± 5.5 % std. dev. Temperature: ± 0.2 K.

METHOD/APPARATUS/PROCEDURE: <p>The dynamic method was used for the determination of solubility. It involved the saturation of nitrogen with tetrachloromethane vapor which was then bubbled through a thermostatically controlled flask filled with a definite volume of the aqueous solution. After 2 - 3 hours the solution became saturated and samples were taken periodically (ref. 1). The concentration of tetrachloromethane in the aqueous solution was determined by gas chromatography. On average 3 - 5 measurements were taken at each temperature.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Source and purity not given. AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The equilibrium between a known volume of tetrachloromethane gas and KOH solution was established in a container under continuous shaking. The volume of tetrachloromethane not dissolved in the KOH solution was measured and the amount of dissolved gas was determined at the same time and conditions. A single measurement was done at each temperature.		SOURCE AND PURITY OF MATERIALS: (1) Prepared in the authors' laboratory; purified by fractional distillation before use. ---	--

CRITICAL EVALUATION:

All the available solubility data for bromodichloromethane (1) in water (2) are summarized in Table 1.

The data are in very poor agreement and in the absence of other independent studies it is not possible to determine which values are the more reliable. Further studies will be necessary before even tentative values can be assigned. Even so, it may be observed that the solubility trend for halogenated hydrocarbon - water systems, as presented in the Preface, provided some support for the mass per cent (1) value, 100 w₁, of 1.618 at 298.15 K (ref. 1).

Table 1. Reported Solubility of Bromodichloromethane (1) in Water (2)

Temperature		Reported Solubility	
°C	K	100 w ₁	10 ³ x ₁
20	293.15	2.099 (ref. 4)	2.352 (ref. 4)
24.85	298.00	1.821 (ref. 5)	2.035 (ref. 5)
25	298.15	1.618 (ref. 1)	1.805 (ref. 1)
30	303.15	0.3023 (ref. 2), 0.2972 (ref. 3)	0.3333 (ref. 2), 0.3277 (ref. 3)

METHOD/APPARATUS/PROCEDURE: The apparatus consisted of a stripping vessel similar to that described by Mackay <i>et al.</i> (ref. 1). The air entered through the top of the vessel and the diffuser was close to the bottom. The solution was added to the stripping vessel and the desired flow was maintained. Samples of the solution being stripped were taken for analysis. After extraction of the sample, the extracts were analyzed by a gas chromatograph equipped with a capillary column.		SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled and deionized.	
		ESTIMATED ERRORS: Solubility: $\pm 0.2 \times 10^{-3}$ std. dev. Temperature: $\pm 0.1\text{ K}$.

COMPONENTS: (1) Dibromochloromethane; CHBr ₂ Cl; [124-48-1] (2) Water; H ₂ O; [7732-18-5]	EVALUATOR: A. L. Horvath, Imperial Chemical Industries Limited, Runcorn, U.K. January 1993.
---	---

CRITICAL EVALUATION:

All the available solubility data for dibromochloromethane (1) in water (2) are summarized in Table 1.

The data are in very poor agreement. Considerable discrepancies exist even between the two solubility values reported by the same workers, compare (ref. 2) and (ref. 3). In the absence of further independent studies, it is not possible to determine which value is the more reliable. Additional investigations will be necessary before even tentative values can be assigned. Even so, it may be noted that the solubility trend for halogenated hydrocarbon - water systems, as presented in the Preface, provided some support for the mass per cent (1) value, 100 w₁, of 0.8124 at 298.15 K (ref. 1).

Table 1. Reported Solubility of Dibromochloromethane (1) in Water (2)

Temperature		Solubility	
°C	K	100 w ₁	10 ⁴ x ₁
10	283.15	0.3040 (ref. 6)	2.637 (ref. 6)
20	293.15	0.6320 (ref. 4), 0.2375 (ref. 6)	5.498 (ref. 4), 2.059 (ref. 6)
24.85	298.00	1.423 (ref. 5)	12.470 (ref. 5)
25	298.15	0.8124 (ref. 1)	7.079 (ref. 1)
30	303.15	0.1049 (ref. 2), 0.2514 (ref. 3) 0.3132 (ref. 6)	0.9082 (ref. 2), 2.179 (ref. 3) 2.7168 (ref. 6)

AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: <p>250 cm³ bottles were filled with distilled deionized water and sealed. A measured volume of dibromochloromethane was injected into the bottles through each bottle septum using a microliter syringe. The solute was in excess of the anticipated solubility limit. The bottles were shaken for one hour with a wrist-action shaker and allowed to equilibrate for about three weeks. Samples were then injected into a gas chromatograph equipped with a Carbowack column and a FID detector. The GC response was compared with the calibration plot.</p>	SOURCE AND PURITY OF MATERIALS: (1) Probably a commercial reagent, at least 99 % purity, used as received. (2) Distilled and deionized. <hr/> ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 0.5 K (compiler).

COMPONENTS:

- (1) Tribromomethane (bromoform);
CHBr₃; [75-25-2]
- (2) Water; H₂O; [7732-18-5]

EVALUATOR:

A. L. Horvath, Imperial Chemical Industries
Limited, Runcorn, U.K.

February 1993.

CRITICAL EVALUATION:

The tribromomethane (1) and water (2) binary system is discussed in two parts; part 1 is tribromomethane (1) in water (2) and part 2 is water (2) in tribromomethane (1).

Part 1. All the available data for the solubility of tribromomethane (1) in water (2) were considered acceptable for use in the smoothing equation except the following reported values. The datum of Squire and Caines (ref. 1) is rejected because of the lack of details on the purity of the sample, method of the experimental work, and significant deviation from other measurements. The approximate value of Booth and Everson (ref. 2) is also rejected because it is significantly lower than later studies. The datum of McNally and Grob (ref. 3) is rejected because the reported solubility is rather higher than other determinations. The data of Wright *et al.* (ref. 4) are contrary to the general trend of the temperature dependence of the solubilities in water (formation of maximum) and are rejected.

The remaining data, mainly at 298 K, are in reasonable agreement although further studies are required before any values can be recommended without qualification.

The tentative solubility values in mass per cent for tribromomethane (1) in water (2) over the 283 to 303 K temperature range were used to obtain the following equation:

$$\text{Solubility } [100 w_1] = 2.371 - 0.01517 (T/K) + 2.7808 \times 10^{-5} (T/K)^2$$

This regression equation was established using the combined data from (refs. 5 - 12), which yielded a standard deviation of 1.6×10^{-2} .

The tentative solubility values in mass per cent at 5 K intervals for tribromomethane (1) in water (2) are presented in the Table 1.

The curve obtained from the smoothing equation is shown in Figure 1. It should be noted that the solubility minimum, which is discussed in the Preface, appearing in the 283 to 303 K temperature interval is not pronounced.

Figure 1. Solubility of Tribromomethane (1) in Water (2).

(continued next page)

COMPONENTS:

(1) Tribromomethane (bromoform);
CHBr₃; [75-25-2](2) Water; H₂O; [7732-18-5]

EVALUATOR:

A. L. Horvath, Imperial Chemical Industries
Limited, Runcorn, U.K.

February 1993.

CRITICAL EVALUATION: (continued)

Table 1. Tentative Solubility of Tribromomethane (1) in Water (2)

Temperature °C	K	Solubility	
		100 w ₁	10 ⁴ x ₁
10	283.15	0.305	2.18
15	288.15	0.309	2.21
20	293.15	0.314	2.24
25	298.15	0.320	2.29
30	303.15	0.328	2.34

Part 2. The only datum available for the solubility of water (2) in tribromomethane (1) is that of Mackay *et al.* (ref. 9); therefore, no Critical Evaluation is possible. The interested reader is referred to the relevant Compilation Sheet for the experimental solubility.

AUXILIARY INFORMATION									
METHOD/APPARATUS/PROCEDURE: The equilibrium was ensured by repeated shaking and centrifuging of a tribromomethane and water mixture in a stoppered Goetz tube and returning it to a constant temperature water bath. The difference between the total amount of tribromomethane which was added and the amount remaining in excess was taken as the amount of tribromomethane dissolved in the known volume of water. The determination of the excess amount of tribromomethane added is described by Hamslick (ref. 1).	SOURCE AND PURITY OF MATERIALS: (1) Source not given. Commercial reagent, C. P. grade, used as received. (2) Distilled. ESTIMATED ERRORS: Solubility: $< 100 \%$. Temperature: $\pm 1 \text{ K}$ (compiler). REFERENCES: (1) Hamslick, R. S. <i>Ph. D. AUXILIARY INFORMATION													
METHOD/APPARATUS/PROCEDURE: <p>An aqueous solution with an excess of tri-bromomethane was stirred for 1 day before being introduced into a 1 liter glass vessel. Nitrogen entered at the bottom of the vessel through a sintered glass disk. The exit gas flow rate was measured by a soap bubble flow meter. The concentration of tri-bromomethane in water was determined by gas chromatography. The GC was equipped with both dual flame ionization detector and an electron capture detector.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Doubly distilled. METHOD/APPARATUS/PROCEDURE: <p>The original method and apparatus for the determination of Henry's law constants, described by Mackay <i>et al.</i> (ref. 1), were used. The general procedure was to add an excess quantity of tribromomethane to distilled deionized water and mix the system overnight. A portion of the solution was returned to the stripping vessel. Tribromomethane was stripped isothermally from the solution at a known gas flow rate. The Henry's law constant was calculated from the log of the concentration versus time plot. The experimental data values are averages of two or more replicates.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source not given. CRITICAL EVALUATION:

The trichloromethane (1) and water (2) binary system is discussed in two parts; part 1 is trichloromethane (1) in water (2) and part 2 is water (2) in trichloromethane (1).

Part 1. The solubility of trichloromomethane (1) in water (2) has been studied by 54 workers with reasonable agreement of reported values from a majority of the investigators.

The experimental data of most investigators in the 273 to 333 K temperature interval are sufficiently reliable to use in the smoothing equation, see Figure 1. (The solid curve in the figure was obtained from the regression of all values shown in the figure.) The experimental work of several workers was not used for the smoothing equation for a variety of reasons. The solubility data of Herz (ref. 1), Salkowski (ref. 2), Ababi *et al.* (ref. 3), Svetlanov *et al.* (ref. 4), Sato and Nakijima (ref. 5), Veith *et al.* (ref. 6), McNally and Grob (ref. 7), and Howe *et al.* (ref. 8) are markedly lower than other results and are therefore rejected. The data of McCollum (ref. 9), Booth and Everson (ref. 10), Arefeva *et al.* (ref. 11), Coca *et al.* (ref. 12), and Warner *et al.* (ref. 13) are several per cent higher than the smoothed solubility values and are also rejected. Although, the measured solubility data of Okuda (ref. 14) above 310 K are in reasonable agreement, the low temperature data, that is, below 303 K are very uncertain. Consequently, the low temperature data were not included in the regression analysis. Similar inconsistency was found in the data of Hunter-Smith *et al.* (ref. 15) and were excluded from further considerations. Lincoff and Gossett (ref. 16) presented two methods for the determination of the solubility. The data determined by the Batch Air Stripping method shows more compatible results and are in good agreement, whereas it appears the EPICS method gave values too low. Therefore, only the solubility data measured by the Batch Air Stripping method were used for fitting the regression equation.

The combined data of 40 laboratories were correlated to obtain the following mass per cent (1) equation:

$$\text{Solubility [100 } w_1] = 12.5333 - 7.40557 \times 10^{-2} (T/K) + 1.16374 \times 10^{-4} (T/K)^2$$

which shows a standard deviation of 5.6×10^{-2} . This equation, which shows a maximum deviation of 18 % (but much less for most of the data), may be considered as representing the combined solubility values in the 273 to 333 K temperature range.

The solubility minimum (see Figure 1) calculated from the regression equation is, in mass per cent (1), 0.752 at 318.18 K. The presence of a minimum in the solubility versus temperature behavior for the halogenated hydrocarbon-water systems is discussed in the Preface.

The recommended solubility values in mass per cent at 5 K intervals for trichloromomethane (1) in water (2) are presented in Table 1.

Table 1. Recommended Solubility of Trichloromethane (1) in Water (2)

Temperature		Solubility	
°C	K	100 w_1	$10^3 x_1$
0	273.15	0.988	1.503

CRITICAL EVALUATION: (continued)

Figure 1. Solubility of Trichloromethane (1) in Water (2).

Part 2. The solubility of water (2) in trichloromomethane (1) has been studied by 25 workers as recorded in the Compilation Sheets immediately following this Critical Evaluation. The reported solubilities in the 263 to 323 K temperature interval are quite acceptable for using the smoothing equation as seen in Figure 2.

All the available data for the solubility of water (2) in trichloromomethane (1) have been included for the fitting of the correlating equation with the following exceptions. The measured data of Herz (ref. 1), Evans (ref. 17), De Minjer (ref. 18), Reinders and De Minjer (ref. 19), and Kudryavtseva and Krutikova (ref. 20) are rejected because they are significantly higher than later studies. The data of Donahue and Bartell (ref. 21), Tettamanti *et al.* (ref. 22), Christyakov and Shapurova (ref. 23), and Antropov *et al.* (ref. 24) are markedly lower than other determinations and are therefore rejected.

The remaining data of 16 laboratories are in good agreement and the correlated values above 253 K are recommended although the low temperature data (below 273 K) are probably dubious. Further studies are required to establish reliable values in the lower temperature range below 273 K.

The equation for the mass per cent solubility of water (2) in trichloromomethane (1) between 263 and 323 K is as follows:

$$\text{Solubility [100 } w_1] = 6.1195 \times 10^2 - 2.0623 \times 10^3 (T/K) + 7.20879 \times 10^6 (T/K)^2$$

This equation represents the combined data with a standard deviation of 2.2×10^{-2} and a correlation coefficient of 0.916.

The recommended mass per cent solubility values at 5 K intervals for water (2) in trichloromomethane (1) are presented in the Table 2.

(continued next page)

COMPONENTS:

(1) Trichloromethane (chloroform);
CHCl₃; [67-66-3](2) Water; H₂O; [7732-18-5]

EVALUATOR:

A. L. Horvath, Imperial Chemical Industries
Limited, Runcorn, U.K.

March 1993.

CRITICAL EVALUATION: (continued)

The curve obtained from the smoothing equation is shown in Figure 2. It may be noted that all the studies show a general increase in the solubility with temperature, which is consistent with the discussion of water solubility versus temperature in the Preface. Often the temperature dependence of the solubility is plotted on a Cox chart, that is, $\log_{10} x_2$ versus $1/T$, where a straight line represents the solubility behavior. This procedure is very useful for the illustration of data covering a limited temperature range. However, for the water (2) trichloromethane (2) system, this method of correlation was found to be less satisfactory than the regression with the normal polynomial equation.

Table 2. Recommended Solubility of Water (2) in Trichloromethane (1)

Temperature °C	Temperature K	Solubility	
		100 w_1	$10^3 x_2$
-10	263.15	0.0177	1.172

METHOD/APPARATUS/PROCEDURE: <p>A colorimetric method was used. A 2.5 g trichloromethane sample was pipetted into a centrifuge tube containing 20 cm^3 water. The tube was then vigorously shaken in a thermostat bath for 2 days. After shaking, the tube was centrifuged at high speed to give a clear upper water layer. From this layer the concentration of trichloromethane was determined by using a colorimetric method.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled (compiler). ESTIMATED ERRORS: Solubility: $\pm 1\%$. Temperature: $\pm 1 \text{ K}$ (compiler).

METHOD/APPARATUS/PROCEDURE: An oil centrifuge bottle (so-called) which permitted an accurate reading of both the total volume and the small volume of upper or lower layer was used for the measurements. The necks of the solubility bottles were graduated to 0.05 cm^3 over a 5 cm^3 volume range. These bottles held approximately 50 cm^3 . Following the Hill method, weighted amounts of the two liquids were introduced into the bottles and shaken until equilibrium was reached. AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: A 1 to 15 volume ratio mixture of water and trichloromethane was introduced into an equilibration flask and then lowered into a water thermostat bath. The assembly was shaken mechanically for about 90 minutes at constant temperature. The amount of water in the organic phase was determined by a modified Karl Fischer titration. The measurement was done in triplicate. The description was taken from a secondary source (ref. 1), because the original report is no longer available.		SOURCE AND PURITY OF MATERIALS: (1) Distilled. (2) Source not given. Purified and dried before use.	
		ESTIMATED ERRORS: Solubility: ± 0.1 × 10 ⁻⁴ avg. dev. Temperature: ± 0.05 K.

AUXILIARY INFORMATION																																	
METHOD/APPARATUS/PROCEDURE: <p>The direct injection technique was used for the investigation of the solubility of trichloromethane in water. Ostwald coefficients were determined by equilibration of trichloromethane with water in a capped syringe. After thoroughly mixing, a sample was withdrawn and analyzed in a gas chromatograph equipped with a hydrogen flame detector. The concentration was proportional to the recorded peak height.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled. <hr/> ESTIMATED ERRORS: Solubility: Not specified. AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: <p>The dynamic method was used for the determination of the solubility. It consisted of the saturation of nitrogen with trichloromethane vapor which was then bubbled through a thermostatically controlled flask filled with a definite volume of water. After 2 - 3 hours the solution became saturated and samples were taken periodically (ref. 1). The concentration of trichloromethane in water was determined by GLC. On average, 3 - 5 measurements were taken at each temperature.</p>		SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled (compiler).

METHOD/APPARATUS/PROCEDURE: <p>The Alexejev's synthetic method of solubility determination was used (ref. 1). A fixed weight of trichloromethane and water was sealed in a tube and subjected to gradually increasing temperature with constant agitation. The appearance of opalescence or clouding was the indication of the saturation temperature. The temperature was then allowed to fall and, while the tube was constantly agitated, the temperature of the first appearance of opalescence was recorded. The observation was repeated several times.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled. <hr/> ESTIMATED ERRORS: Solubility: Not specified. AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: <p>The original method and apparatus for the determination of Henry's law constants have been described elsewhere (ref. 1). The general procedure was to add an excess of trichloromethane to distilled, deionized water and, following, to mix the system overnight. A portion of the solution was returned to the stripping vessel. Trichloromethane was stripped isothermally from the solution at a known gas flow rate. The Henry's law constant was calculated from the log of the concentration versus time plot. The experimental data values are averages of two or more replicates.</p>	SOURCE AND PURITY OF MATERIALS: (1) Purest quality available and was used without further purification, that is > 99 %. AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: <p>250 cm³ bottles were filled with distilled deionized water and sealed. A measured volume of trichloromethane was injected into the bottles through each bottle septum using a microliter syringe. Trichloromethane was in excess of the anticipated solubility limit. The bottles were shaken for 1 hour with a wrist-action shaker and allowed to equilibrate for about 3 weeks. Samples were then injected into a gas chromatograph equipped with a Carbo-pack column and a FID detector. The GC response was compared with the calibration plot.</p>	SOURCE AND PURITY OF MATERIALS: (1) Probable a commercial reagent at least 99 % purity. Used as received. (2) Distilled and deionized. ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 0.5 K (compiled).

AUXILIARY INFORMATION																																									
METHOD/APPARATUS/PROCEDURE: The dynamic method which was used for the solubility determination consisted of the saturation of nitrogen with the solute vapor which was then bubbled through a thermostatically controlled flask filled with a definite volume of trichloromethane. After 2 - 3 hours, the solution became saturated and samples were taken periodically (ref. 1). The trichloromethane concentration in the aqueous solution was determined by GLC. On average, 3 - 5 measurements were taken at each temperature.	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Source and purity not given. (3) Distilled (compiler). AUXILIARY INFORMATION																																				
METHOD/APPARATUS/PROCEDURE: A 1 to 15 volume ratio mixture of heavy water and trichloromethane was introduced into an equilibration flask and then lowered into a water thermostat. The assembly was shaken mechanically for about 90 minutes at constant temperature. The amount of heavy water in the organic phase was determined by a modified Karl Fischer titration method. The determination was done in triplicate. The description was taken from a secondary source (ref. 1). The original report is no longer available.	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Source not given. Purified and dried before use. ESTIMATED ERRORS: Solubility: $\pm 0.6 \times 10^{-4}$ avg. dev. Temperature: $\pm 0.05\text{ K}$.

METHOD/APPARATUS/PROCEDURE: Excess triiodomethane in 5 cm^3 water samples were enclosed in small vials which, when stoppered, were shaken until equilibria were established. The solutions were filtered into weighed crucibles and reweighed. After drying in vacuum desiccators, the crucibles were again weighed and the loss of water calculated. No great accuracy was claimed for the experiments.		SOURCE AND PURITY OF MATERIALS: (1) From reliable firms; "not always pure." (2) Distilled (compiler).

<p>CRITICAL EVALUATION:</p> <p>The bromochloromethane (1) and water (2) binary system is discussed in two parts; part 1 is bromochloromethane (1) in water (2) and part 2 is water (2) in bromochloromethane (1).</p> <p>The solubility of bromochloromethane (1) in water (2) has been studied by three workers, whereas the solubility of water (2) in bromochloromethane (1) has been reported in one paper only.</p> <p>Part 1. The solubility of bromochloromethane (1) in water (2) has been studied by three workers. The experimental data of Tewari <i>et al.</i> (ref. 1) and Miller <i>et al.</i> (ref. 2) are in excellent agreement and the mass per cent (1) value of 1.646 at 298.15 K is recommended. In both cases the modified generator column method was used, but the analytical method was more advanced in the latter case. (For a comparison, see the two compilation sheets.) The single mass per cent (1) data point of 1.5 g(1)/100 g soln. at 293.15 K, reported by O'Connell (ref. 3) is considered as tentative. Whether the solubilities at 293.15 and 298.15 K are consistent with the general trend of temperature dependence remains to be investigated.</p> <p>Part 2. The solubility of water (2) in bromochloromethane (1) has been reported in only one paper, that of O'Connell (ref. 3) and there are no other measurements for comparison. Therefore, it is not possible to perform a critical evaluation. The readers are referred to the compilation sheet for further details.</p> <p>REFERENCES:</p> <p>23 1. Tewari, Y. B.; Miller, M. METHOD/APPARATUS/PROCEDURE: <p>A saturated aqueous solution was prepared by passing water through a column which was packed with glass beads coated with bromochloromethane. The saturated solution was then pumped through an extractor column and bromochloromethane was extracted into an analytical column. The samples were analyzed with a liquid chromatograph equipped with both an UV absorbance and a fluorescent detector with excitation filters. The peak area was established using a Hewlett-Packard integrator.</p>	SOURCE AND PURITY OF MATERIALS: (1) Eastman Kodak Co., Commercial quality, used as received. (2) Double distilled. ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 1 K (compiler).								

COMPONENTS: (1) Dibromomethane; CH ₂ Br ₂ ; [74-95-3] (2) Water; H ₂ O; [7732-18-5]	EVALUATOR: A. L. Horvath, Imperial Chemical Industries Limited, Runcorn, U.K. March 1993.
---	--

CRITICAL EVALUATION:

The dibromomethane (1) and water (2) binary system is discussed in two parts; part 1 is dibromomethane (1) in water (2) and part 2 is water (2) in dibromomethane (1).

Part 1. The solubility of dibromomethane (1) in water (2) has been studied by 6 workers. The Compilation Sheets immediately follow this Critical Evaluation.

The experimental data of all investigators in the 273 to 323 K temperature range are sufficiently reliable for use in the smoothing equation (see Figure 1) with the exception of the experimental work of Booth and Everson (ref. 1) which is markedly higher than other results and is therefore rejected. The combined data of 5 laboratories were correlated to give the following equation for mass per cent (1) solubility:

$$\text{Solubility } [100 w_1] = 10.1890 - 0.06336789 (T/K) + 1.10906 \times 10^{-4} (T/K)^2$$

which produced a standard deviation of 4.4×10^{-2} . This equation represents the combined solubility data with a maximum deviation of 6.0 % (usually less) and may be considered recommended to represent the data in the 273 to 323 K temperature interval.

The recommended mass per cent solubility values at 5 K intervals for dibromomethane (1) in water (2) are recorded in Table 1.

Table 1. Recommended Solubility of Dibromomethane (1) in Water (2)

Temperature		Solubility	
°C	K	100 w ₁	10 ³ x ₁
0	273.15	1.155	1.209
5	278.15	1.144	1.198
10	283.15	1.138	1.191
15	288.15	1.138	1.191
20	293.15	1.144	1.198
25	298.15	1.155	1.209
30	303.15	1.171	1.226
35	308.15	1.194	1.251
40	313.15	1.221	1.279
45	318.15	1.254	1.313
50	323.15	1.293	1.356

Part 2. The solubility of water (2) in dibromomethane (1) has been reported in one work (ref. 2) and, therefore, no Critical Evaluation has not been performed. The readers are referred to the relevant Compilation Sheet.

AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: A differential static cell equilibrium apparatus was used to measure the infinite dilution activity coefficient for dibromomethane (<i>γ</i> [∞]) in water. Degassed water cells were submerged in a thermostated water bath. Dibromomethane was injected into a mixture cell, a magnetic stirrer was turned on, and the cells were allowed to equilibrate. The stirrer was then turned off and the differential pressure was recorded. The experiment was repeated at least three times at each temperature.	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled, filtered and deionized. ESTIMATED ERRORS: Solubility: See above. Temperature: ± 0.05 K.																

<p>COMPONENTS:</p> <p>(1) Dichloromethane; CH₂Cl₂; [75-09-2]</p> <p>(2) Water; H₂O; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>A. L. Horvath, Imperial Chemical Industries Limited, Runcorn, U.K.</p> <p>March 1993.</p>																																								
<p>CRITICAL EVALUATION:</p> <p>The dichloromethane (1) and water (2) binary system is discussed in two parts; part 1 is dichloromethane (1) in water (2) and part 2 is water (2) in dichloromethane (1).</p> <p>Part 1. The solubility of dichloromethane (1) in water (2) has been studied by at least 32 groups of workers. Most of the data reported have been considered for inclusion in the smoothing equation with the following exclusions. The experimental data of Salkowski (ref. 1) are markedly lower than the other results and are therefore rejected. The solubility data of Booth and Everson (ref. 2), Alexandrova <i>et al.</i> (ref. 3), and Sadovnikova <i>et al.</i> (refs. 4 and 5) are several per cent higher than the smoothed solubility values and are also rejected. The data of Sabinin <i>et al.</i> (ref. 6) between 293.15 and 303.15 K show a temperature dependence of solubility much too large and are therefore rejected. The data of Svetlanov <i>et al.</i> (ref. 7) also show a change in solubility far too large between 288.15 and 333.15 K and are rejected; however, the value at 303.15 K is retained. The solubilities calculated from the distribution coefficients of Prosyantov <i>et al.</i> (ref. 8) are in very poor agreement, providing no confidence in their values which are regarded as dubious. The solubility data of Howe <i>et al.</i> (ref. 9) between 283.15 and 303.15 K show a maximum which is inconsistent with the trend of temperature dependence of solubility and are rejected; however, the value at 293.15 K is retained.</p> <p>The remaining data of 25 laboratories by Rex (ref. 10), van Arkel and Vles (ref. 11), Bakowski and Treszczanowicz (ref. 12), Niini (ref. 13), McGovern (ref. 14), Donahue and Bartell (ref. 15), Kudryavtseva and Krutikova (ref. 16), Maretic and Sirocic (ref. 17), du Pont (ref. 18), Svetlanov <i>et al.</i> (ref. 7), Karger <i>et al.</i> (ref. 19), Antropov <i>et al.</i> (ref. 20), McConnell <i>et al.</i> (ref. 21), Pearson and McConnell (ref. 22), Anchor and Stevens (ref. 23), Sato and Nakijima (ref. 24), Coca <i>et al.</i> (ref. 25), Hutchinson <i>et al.</i> (ref. 26), Leighton and Calo (ref. 27), Lincoff and Gossett (ref. 28), Gossett (ref. 29), Warner <i>et al.</i> (ref. 30), Howe <i>et al.</i> (ref. 9), Vogel (ref. 31), and Wright <i>et al.</i> (ref. 32), were used to obtain the following smoothing equation for solubility in mass per cent (1):</p> $\text{Solubility [100 } w_1] = 58.838 - 0.38224 (T/K) + 6.3928 \times 10^{-4} (T/K)^2$ <p>This equation represents the combined data with a 0.37 standard deviation in the 273 to 310 K temperature range.</p> <p>The curve obtained from the smoothing equation shows a distinct minimum at 299 K as seen in Figure 1. The appearance of the minimum for the solubility versus temperature behavior is discussed in the Preface.</p> <p>The recommended mass per cent solubility values at 5 K intervals for dichloromethane (1) in water (2) are presented in the Table 1.</p> <p style="text-align: center;">Table 1. Recommended Solubility of Dichloromethane (1) in Water (2)</p> <table border="1" style="margin-left: auto; margin-right: auto;"> <thead> <tr> <th colspan="2">Temperature</th> <th colspan="2">Solubility</th> </tr> <tr> <th>°C</th> <th>K</th> <th>100 w_1</th> <th>10³ x_1</th> </tr> </thead> <tbody> <tr><td>0</td><td>273.15</td><td>2.126</td><td>4.587</td></tr> <tr><td>5</td><td>278.15</td><td>1.977</td><td>4.260</td></tr> <tr><td>10</td><td>283.15</td><td>1.860</td><td>4.004</td></tr> <tr><td>15</td><td>288.15</td><td>1.766</td><td>3.799</td></tr> <tr><td>20</td><td>293.15</td><td>1.722</td><td>3.703</td></tr> <tr><td>25</td><td>298.15</td><td>1.701</td><td>3.657</td></tr> <tr><td>30</td><td>303.15</td><td>1.712</td><td>3.681</td></tr> <tr><td>35</td><td>308.15</td><td>1.754</td><td>3.773</td></tr> </tbody> </table> <p style="text-align: right;">(continued next page)</p>		Temperature		Solubility		°C	K	100 w_1	10 ³ x_1	0	273.15	2.126	4.587	5	278.15	1.977	4.260	10	283.15	1.860	4.004	15	288.15	1.766	3.799	20	293.15	1.722	3.703	25	298.15	1.701	3.657	30	303.15	1.712	3.681	35	308.15	1.754	3.773

COMPONENTS: (1) Dichloromethane; CH ₂ Cl ₂ ; [75-09-2] (2) Water; H ₂ O; [7732-18-5]	EVALUATOR: A. L. Horvath, Imperial Chemical Industries Limited, Runcorn, U.K. March 1993.
--	--

CRITICAL EVALUATION: (continued)

Figure 1. Solubility of Dichloromethane (1) in Water (2).

Part 2. The solubility of water (2) in dichloromethane (1) has been reported from 19 laboratories. The solubility measurements cover the 253 to 313 K temperature range as represented in Figure 2.

The data reported have been considered for inclusion in the smoothing equation with the following exclusions. The data of Bakowski and Terszczanowicz (ref. 12), Niini (ref. 13), Donahue and Bartell (ref. 15), and Kudryavtseva and Krutikova (ref. 16) are markedly higher than other results and are therefore rejected. The measured solubility of Alexandrova *et al.* (ref. 3), and Sadovnikova *et al.* (refs. 4 and 5) are several per cent lower than the smoothed solubility and are also rejected. The solubilities calculated from the distribution coefficients of Prosyantov *et al.* (ref. 33), are in very poor agreement, providing no confidence in their values which are regarded as dubious.

The remaining data of 11 laboratories by Staverman (Ref. 34), McGovern (ref. 14), Davies *et al.* (ref. 35), Maretic and Sirocic (ref. 17), Sabinin *et al.* (ref. 6), Lees and Sarram (ref. 36), Antropov *et al.* (ref. 20), Archer and Stevens (ref. 23), Coca *et al.* (ref. 25), Wu (ref. 37), and Ohtsuka and Kazama (ref. 38) were compiled or used for the smoothing equation. The fitting equation used was:

$$\log_{10} x_2 = 1.8214 - 1164.63/(TK)$$

The equation represents the combined data with a standard deviation of 5.8×10^{-2} in the 253 to 313 K temperature range.

The recommended mass per cent solubility values at 5 K intervals for water (2) in dichloromethane (1) are presented in the Table 2.

The linear relation between the solubility expressed as $\log_{10} x_2$ versus the reciprocal of absolute temperature behavior is illustrated in Figure 2. The straight line behavior of such plots is characteristic of the solubility of water in halogenated hydrocarbons, as discussed in the Preface.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE: Equilibrium was ensured through repeated shaking and centrifuging of a dichloromethane and water mixture in a stoppered Goetz tube and returning the sample to a constant temperature water bath. The difference between the total amount of dichloromethane which was added and the amount remaining in excess was taken as the amount of dichloromethane dissolved in the known volume of water. The determination of the excess amount of dichloromethane added is described by Hanslick (ref. 1).	SOURCE AND PURITY OF MATERIALS: (1) Commercial reagent, C. P. grade, used as received. (2) Distilled.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: A dynamic method was used for the solubility determination. It consisted of the saturation of nitrogen with dichloromethane vapor which was then bubbled through a thermostatically controlled flask filled with a definite volume of water. After 2 - 3 hours, the solution became saturated and samples were taken periodically (ref. 1). The concentration of dichloromethane in water was determined by gas-liquid chromatography. On average, 3 - 5 measurements were taken at each temperature.		SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled (compiler).		
		ESTIMATED ERRORS: Solubility: ± 15 %. Temperature: ± 0.05 K.

METHOD/APPARATUS/PROCEDURE: Alexejev's synthetic solubility determination method was used (ref. 1). A fixed weight of dichloromethane and water was sealed in a tube and the mixture was subjected to gradually increasing temperature with constant agitation. The appearance of opalescence or clouding was the indication of the saturation temperature. The temperature was then allowed to fall and an observation made, while the tube was constantly agitated, of the temperature of the first appearance of opalescence. The observation was repeated several times.	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The mutual solubility data were determined by the method described by Othmer <i>et al.</i> (ref. 1). A 10 cm ³ dichloromethane sample was added to water from a buret and agitated until the solution became turbid. The appearance of the turbidity indicated the formation of a second phase. The solubilities were calculated by means of known densities and volumes.		SOURCE AND PURITY OF MATERIALS: (1) Probus reagent, further purified by distillation in a heli-packing column. (2) Distilled.		
		ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 0.5 K (compiler).

AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: Henry's law constants were determined by EPICS and Batch Air Stripping methods. The Equilibrium Partitioning in Closed Systems (EPICS) technique compared the GL peak heights upon direct injection of headspace samples. For the Batch Air Stripping procedure, equal volume samples were placed in serum bottles and allowed to reach equilibrium. The equilibrated headspaces containing concentrations proportional to original concentrations in the aqueous samples were analyzed. Full equilibrium was achieved in a few hours. AUXILIARY INFORMATION																										
METHOD/APPARATUS/PROCEDURE: <p>A modification of the EPICS (Equilibrium Partitioning in Closed Systems) procedure was used for measuring Henry's law constants. A precise quantity of dichloromethane was injected into serum bottles which contained distilled water. The bottles were incubated for 18 - 24 hours at four desired temperatures in a reciprocating shaker bath. The headspace concentrations of the EPICS bottles were measured using a gas chromatograph which was equipped with a flame ionization detector. The mean of the coefficient of variation values was approximately 4.3 %.</p>	SOURCE AND PURITY OF MATERIALS: (1) Burdick & Jackson reagent, pesticide grade. Distilled in a glass set-up before use. AUXILIARY INFORMATION																										
METHOD/APPARATUS/PROCEDURE: <p>The original method and apparatus for the determination of Henry's law constant, as described by Mackay <i>et al.</i> (ref. 1), was used. The general procedure was to add an excess quantity of dichloromethane to distilled deionized water, place the sample in a thermostat bath, and provide overnight mixing. A portion of this solution was returned to the stripping vessel. Dichloromethane was stripped isothermally from the solution at a known gas flow rate. The Henry's law constant was calculated from the log of the concentration versus time plot. The experimental data values are averages of two or more replicates.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source not given. Purest quality available, used as received. Stated purity > 99 %. (2) Distilled and deionized.																									
ESTIMATED ERRORS: Solubility: ± 6 % std. dev. Temperature: ± 0.05 K.

AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: <p>250 cm³ bottles were filled with distilled deionized water and sealed. Measured volumes of dichloromethane were injected into the bottles through each bottle septum using a microliter syringe. Dichloromethane was in excess of the anticipated solubility limit. The bottles were shaken for one hour with wrist-action shaker and allowed to equilibrate for about 3 weeks. Samples were than injected into a gas chromatograph equipped with a Carbo-pack column and a FID detector. The GL response was compared with the calibration plot.</p>	SOURCE AND PURITY OF MATERIALS: (1) Probably a commercial reagent at least 99 % pure. Used as received. (2) Distilled and deionized. <hr/> ESTIMATED ERRORS: Solubility: Not specified. Temperature: ± 0.5 K (compiler).

METHOD/APPARATUS/PROCEDURE: <p>A differential static cell equilibrium apparatus was used to measure the infinite dilution activity coefficient of dichloromethane (γ^{∞}) in water. Cells containing degassed water were submerged in a thermostated water bath. Dichloromethane was injected into the mixture cells and a magnetic stirrer was turned on. The cells were allowed to equilibrate. The stirrer was then turned off and the differential pressure was recorded. The experiment was repeated at least three times at each temperature.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled, filtered and deionized.

METHOD/APPARATUS/PROCEDURE: <p>The dynamic method was used for the determination of the solubility. It consisted of the saturation of nitrogen with dichloromethane vapor which was then bubbled through a thermostatically controlled flask filled with a definite volume of solution. After 2 - 3 hours the solution became saturated and samples were taken periodically (ref. 1). The concentration of dichloromethane in the solution was determined by GLC. On average, 3 - 5 measurements were taken at each temperature.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Source and purity not given. (3) Distilled (compiler). Chem.</i> <u>1964</u> , <i>38</i> , 253.																																				

<p>COMPONENTS:</p> <p>(1) Diiodomethane; CH₂I₂; [75-11-6]</p> <p>(2) Water; H₂O; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>A. L. Horvath, Imperial Chemical Industries Limited, Runcorn, U.K.</p> <p>March 1993.</p>
<p>CRITICAL EVALUATION:</p> <p>The diiodomethane (1) and water (2) binary system is discussed in two parts; part 1 is diiodomethane (1) in water (2) and part 2 is water (2) in diiodomethane (1).</p> <p>Part 1. The solubility of diiodomethane (1) in water (2) has been studied by four groups of workers. The experimental data of Gross and Saylor (ref. 1) and Andrews and Keefer (ref. 2) are supported by the descriptions of the methods used for determining the reported data. Details are not available for methods, apparatus, and procedures used by van Arkel and Vles (ref. 3) and O'Connell (ref. 4) for obtaining the solubility data.</p> <p>The three solubility values, see (refs. 1, 3, and 4), between 293.15 and 303.15 K compare favorably with the selected value, whereas the datum of Andrews and Keefer (ref. 2) at 298.15 K is low and classified as doubtful. More accurate solubility determinations are required, meanwhile, the tentative mas per cent solubility of diiodomethane (1) in water (2) is 0.124 at 303.15 K.</p> <p>Part 2. The only datum available for the solubility of water (2) in diiodomethane (1) is that of Hutchison and Lyon (ref. 5) and so no Critical Evaluation is possible. The interested reader is referred to the relevant Compilation Sheet for the experimental solubility.</p> <p>REFERENCES:</p> <ol style="list-style-type: none"> 1. Gross, P. M.; Saylor, J. H. <i>J. Am. COMPONENTS:

- (1) Iodomethane; CH₃I; [74-88-4]
 (2) Water; H₂O; [7732-18-5]

EVALUATOR:

A. L. Horvath, Imperial Chemical Industries
 Limited, Runcorn, U.K.

March 1993.

CRITICAL EVALUATION:

The solubility of iodomethane (1) in water (2) has been studied by 8 groups of workers; whereas, the solubility of water (2) in iodomethane (1) has not been investigated yet.

The experimental data of Glew (ref. 1) covering the 273 to 323 K temperature range are significantly higher than the likely solubility. Furthermore, the continuous decrease in solubility with temperature between 273 and 323 is not consistent with the formation of a minimum shown by most similar binary systems. Therefore, these data are classed as doubtful and are rejected. The presence of a minimum in the solubility versus temperature behavior for the halogenated hydrocarbon-water systems is discussed in the Preface.

The solubility data of Balls (ref. 2) between 283 and 298 K show a continuous rise with temperature which is contrary to the trends shown by all other investigators and are therefore rejected. The single data point of Liss and Slater (ref. 3) at 293 K is lower than other results and is likewise rejected.

The remaining data of Rex (ref. 4), Fühner (ref. 5), van Arkel and Vles (ref. 6), Swain and Thornton (ref. 7), and Hunter-Smith *et al.* (ref. 8) are in reasonable agreement, although further studies are required before any values can be recommended. The tentative mass per cent solubilities of iodomethane (1) in water (2) over the 273 to 313 K temperature range were used to obtain the following equation:

$$\text{Solubility [100 } w_1] = 19.0036 - 0.11723 (T/K) + 1.95356 \times 10^{-4} (T/K)^2$$

This regression equation was established using the combined data from (refs. 4 - 8), which yielded a standard deviation of 4.3×10^{-2} .

The tentative mass per cent solubility values at 5 K intervals for iodomethane (1) in water (2) are presented in Table 1. The curve obtained from the smoothing equation is shown in Figure 1. It shows a distinct minimum at 300.0 K, as discussed in the Preface.

Table 1. Tentative Solubility of Iodomethane (1) in Water (2)

Temperature,		Solubility,	
°C	K	100 w_1	10 ³ x_1
0	273.15	1.557	2.003
5	278.15	1.510	1.942
10	283.15	1.472	1.893

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The experiment was performed in an Ostwald type solubility apparatus consisting of a gas burette and a solubility pipette. The gas burette containing iodomethane and the solubility pipette filled with water were connected and allowed to equilibrate in a thermostat bath. The volume, pressure, and temperature were monitored and Henry's law constants were calculated. A summary of the experiment is given elsewhere (ref. 1).		SOURCE AND PURITY OF MATERIALS: (1) British Drug House, washed with KOH solution, dried, redistilled and dried again with Ca metal turnings. (2) Gas free, deionizes by ion exchange resin.		
		ESTIMATED ERRORS: Solubility: ± 0.5 %. Temperature: ± 0.2 K.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The measuring apparatus was described by Brown <i>et al.</i> (ref. 1). Iodomethane gas was admitted to the measurement apparatus from a storage bulb by distillation. The gas volume absorbed by water was determined using a gas buret. The temperature was controlled by a water bath and the equilibrium was aided by a magnetic stirrer in the equilibration bulb. The concentration in the solution was calculated from the pressure and volume measured.		SOURCE AND PURITY OF MATERIALS: (1) Eastman Kodak Co., redistilled before use. (2) Double distilled.		
		ESTIMATED ERRORS: Solubility: ± 3 %. Temperature: ± 0.01 K. Pressure: ± 0.05 mmHg.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The measurements involved repeated equilibration of nitrogen with a water sample containing iodomethane. The sample was shaken vigorously at the required temperature in a constant temperature bath for 30 minutes. The equilibrated gas phase was then injected into a gas chromatograph. The experiments were performed at least three times at 10, 15, 20, and 25 °C. Each experiments involved about six equilibrations.		SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled.		
		ESTIMATED ERRORS: Solubility: See above. Temperature: ± 0.5 K (compiler).		

COMPONENTS: (1) Iodomethane; CH ₃ I; [74-88-4] (2) Water; H ₂ O; [7732-18-5]		ORIGINAL MEASUREMENTS: Hunter-Smith, R. J.; Balls, P. W.; Liss, P. S. <i>Tellus</i> 1983 , <i>35B</i> , 170-6.

The Henry's law constant (<i>H</i>) was derived from the best-fit lines of van't Hoff plots: $\log_e H = - \frac{3541}{T(K)} + 10.34$			
AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE: The multiple equilibration technique as described elsewhere (ref. 1) was used to measure the Henry's law constants. A known volume of water in a syringe was shaken with a known volume of pure iodomethane. After equilibration, the headspace was separated and analyzed for the compound of interest. A gas chromatograph fitted with an electron capture detector was used for the analysis.		SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. (2) Distilled.

SOLUBILITY DATA SERIES

- Volume 1 H. L. Clever, *Helium and Neon*
 Volume 2 H. L. Clever, *Krypton, Xenon and Radon*
 Volume 3 M. Salomon, *Silver Azide, Cyanide, Cyanamides, Cyanate, Selenocyanate and Thiocyanate*
 Volume 4 H. L. Clever, *Argon*
 Volume 5/6 C. L. Young, *Hydrogen and Deuterium*
 Volume 7 R. Battino, *Oxygen and Ozone*
 Volume 8 C. L. Young, *Oxides of Nitrogen*
 Volume 9 W. Hayduk, *Ethane*
 Volume 10 R. Battino, *Nitrogen and Air*
 Volume 11 B. Scrosati and C. A. Vincent, *Alkali Metal, Alkaline Earth Metal and Ammonium Halides, Amide Solvents*
 Volume 12 C. L. Young, *Sulfur Dioxide, Chlorine, Fluorine and Chlorine Oxides*
 Volume 13 S. Siekierski, T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Nitrates*
 Volume 14 H. Miyamoto, M. Salomon and H. L. Clever, *Alkaline Earth Metal Halates*
 Volume 15 A. F. M. Barton, *Alcohols with Water*
 Volume 16/17 E. Tomlinson and A. Regosz, *Antibiotics: 1,β-Lactam Antibiotics*
 Volume 18 O. Popovych, *Tetraphenylborates*
 Volume 19 C. L. Young, *Cumulative Index: Volumes 1-18*
 Volume 20 A. L. Horvath and F. W. Getzen, *Halogenated Benzenes, Toluenes and Phenols with Water*
 Volume 21 C. L. Young and P. G. T. Fogg, *Ammonia, Amines, Phosphine, Arsine, Stibine, Silane, Germane and Stannane in Organic Solvents*
 Volume 22 T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Halides in Nonaqueous Solvents*
 Volume 23 T. P. Dirkse, *Copper, Silver, Gold and Zinc, Cadmium, Mercury Oxides and Hydroxides*
 Volume 24 W. Hayduk, *Propane, Butane and 2-Methylpropane*
 Volume 25 C. Hirayama, Z. Galus and C. Guminski, *Metals in Mercury*
 Volume 26 M. R. Masson, H. D. Lutz and B. Engelen, *Sulfites, Selenites and Tellurites*
 Volume 27/28 H. L. Clever and C. L. Young, *Methane*
 Volume 29 H. L. Clever, *Mercury in Liquids, Compressed Gases, Molten Salts and Other Elements*
 Volume 30 H. Miyamoto and M. Salomon, *Alkali Metal Halates, Ammonium Iodate and Iodic Acid*
 Volume 31 J. Eysseltová and T. P. Dirske, *Alkali Metal Orthophosphates*
 Volume 32 P. G. T. Fogg and C. L. Young, *Hydrogen Sulfide, Deuterium Sulfide and Hydrogen Selenide*
 Volume 33 P. Franzosini, *Molten Alkali Metal Alkanoates*
 Volume 34 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part I: Non-cyclic Substitutents*
 Volume 35 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part II: 5-Membered Heterocyclic Substitutents*

- Volume 36 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part III: 6-Membered Heterocyclic Substituents and Miscellaneous Systems*
- Volume 37 D. G. Shaw, *Hydrocarbons with Water and Seawater. Part I: Hydrocarbons C₅ to C₇*
- Volume 38 D. G. Shaw, *Hydrocarbons with Water and Seawater. Part II: Hydrocarbons C₈ to C₃₆*
- Volume 39 C. L. Young, *Cumulative Index: Volumes 20–38*
- Volume 40 J. Hala, *Halides, Oxyhalides and Salts of Halogen Complexes of Titanium, Zirconium, Hafnium, Vanadium, Niobium and Tantalum*
- Volume 41 C.-Y. Chan, I. N. Lepeshkov and K. H. Khoo, *Alkaline Earth Metal Perchlorates*
- Volume 42 P. G. T. Fogg and W. Gerrard, *Hydrogen Halides in Non-aqueous Solvents*
- Volume 43 R. W. Cargill, *Carbon Monoxide*
- Volume 44 H. Miyamoto, E. M. Woolley and M. Salomon, *Copper and Silver Halates*
- Volume 45/46 R. P. T. Tomkins and N. P. Bansal, *Gases in Molten Salts*
- Volume 47 R. Cohen-Adad and J. W. Lorimer, *Alkali Metal and Ammonium Chlorides in Water and Heavy Water (Binary Systems)*
- Volume 48 F. Getzen, G. Hefter and A. Maczynski, *Esters with Water. Part I: Esters 2-C to 6-C*
- Volume 49 F. Getzen, G. Hefter and A. Maczynski, *Esters with Water. Part II: Esters 7-C to 32-C*
- Volume 50 P. G. T. Fogg, *Carbon Dioxide in Non-aqueous Solvents at Pressures Less Than 200 kPa*
- Volume 51 J. G. Osteryoung, M. M. Schreiner, C. Guminski and Z. Galus, *Intermetallic Compounds in Mercury*
- Volume 52 I. Lambert and H. L. Clever, *Alkaline Earth Hydroxides in Water and Aqueous Solutions*
- Volume 53 C. L. Young, *Cumulative Index: Volumes 40–52*
- Volume 54 W. E. Acree, Jr, *Polycyclic Aromatic Hydrocarbons in Pure and Binary Solvents*
- Volume 55 S. Siekierski and S. L. Phillips, *Actinide Nitrates*
- Volume 56 D. Shaw, A. Skrzecz, J. W. Lorimer and A. Maczynski, *Alcohols with Hydrocarbons*
- Volume 57 W. Hayduk, *Ethene*
- Volume 58 W. E. Acree, Jr, *Polycyclic Aromatic Hydrocarbons: Binary Non-aqueous Systems. Part I: Solutes A–E*
- Volume 59 W. E. Acree, Jr, *Polycyclic Aromatic Hydrocarbons: Binary Non-aqueous Systems. Part II: Solutes F–Z*
