IUPAC Solubility Data Series Rates for 1996

Subscriptions:	UK and Europe	Rest of World
Full subscription	£280	\$426
Single volume	£80	\$120

Reduced rates are available to members of IUPAC. Please apply directly to the publisher for details.

Prices include postage by surface mail or, for subscribers in the USA and Canada by Airfreight or in Japan, India, Australia and New Zealand by Air Speeded Post. Airmail rates are available on request.

The IUPAC Solubility Data Series (ISSN 0191-5622) is published quarterly in March, June, September and December by Oxford University Press, Oxford, UK. Annual subscription price is US\$426. The IUPAC Solubility Data Series is distributed by Mercury Airfreight International Ltd., 10 Camptown Road, Irvington, New Jersey 07111-1105, USA. Second Class postage paid at Newark, New Jersey, USA and additional entry points.

US POSTMASTER: send address corrections to IUPAC Solubility Data Series, c/o Mercury Airfreight International Ltd., 10 Camptown Road, Irvington, New Jersey 07111-1105, USA. This issue date is March 1996.

New subscriptions may be registered at any time during the year but will be reckoned as running from January 1st of the year in which the subscription is received. Claims regarding non-receipt of issues must be received within 4 months of publication or date of order, whichever is later. Back issues are available—for information contact Journals Customer Services Department, Oxford University Press, Walton Street, Oxford OX2 6DP.

Order Information

Payment is required with all orders and may be made by the following methods:

Cheque (made payable to Oxford University Press)

National Girobank (Account 500 1056)

Credit Card (Access, Visa, American Express, Diners Club)

Direct Debit: Please send for further details

UNESCO Coupons

Bankers: Barclays Bank plc, PO Box 333, Oxford

Code 20-65-18. Account 00715654

Please send orders to: Journals Subscription Department, Oxford University Press, Walton Street, Oxford OX2 6DP. Tel: +44(0)1865 56767, Fax: +44(0)1865 267485

Any enquires regarding this publication should be addressed to:

INTRODUCTION TO THE SOLUBILITY DATA SERIES

SOLUBILITY OF GASES IN LIQUIDS

NATURE OF THE PROJECT

The Solubility Data project (SDP) has as its aim a comprehensive review of published data for solubilities of gases, liquids and solids in liquids or solids. Data of suitable precision are compiled for each publication on data sheets in a uniform format. The data for each system are evaluated and, where data from independent sources agree sufficiently, recommended values are proposed. The evaluation sheets, recommended values, and compiled data sheets are published on consecutive pages.

COMPILATIONS AND EVALUATIONS

The formats for the compilations and critical evaluations have been standardized for all volumes. A description of these formats follows.

Compilations

The format used for the compilations is, for the most part, self-explanatory. Normally, a compilation sheet is divided into boxes, with detailed contents described below.

Components: Each component is listed according to IUPAC name, formula, and Chemical Abstracts (CA) Registry Number. The Chemical Abstracts name is also included if this differs from the IUPAC name, as are trivial names if appropriate. IUPAC and common names are cross-referenced to Chemical Abstracts names in the System Index.

The formula is given either in terms of the IUPAC or Hill (1) system and the choice of formula is governed by what is usual for most current users: i.e., IUPAC for inorganic compounds, and Hill system for organic compounds. Components are ordered on a given compilation sheet according to:

- (a) saturating components;
- (b) non-saturating components according to chemical families; within carbon compounds, according to increasing carbon number;
- (c) solvents according to chemical families; within carbon compounds, according to increasing carbon number.

In each class, ordering follows the 18-column IUPAC periodic table. The same order is followed in arranging the compilation sheets within a given volume.

Original Measurements: References are abbreviated in the forms given by Chemical Abstracts Service Source Index (CASSI). Names originally in other than Roman alphabets are given as transliterated by Chemical Abstracts. In the case of multiple entries (for example, translations) an asterisk indicates the publication used for compilation of the data.

Variables: Ranges of temperature, pressure, etc. are indicated here.

Prepared by: The names of all compilers are given here.

Experimental Values: Components are described as (1), (2), etc., as defined in the "Components" box. Data are reported in the units used in the original publication, with the exception that modern names for units and quantities are used; e.g., mass per cent for weight per cent; mol dm⁻³ for molar; etc. Usually, only one type of value (e.g., mass per cent) is found in the original paper, and the compiler has added the mole fractions from calculations based on 1989 atomic weights (2) and referenced sources of densities, where necessary. Temperatures are expressed as *t*/°C, *t*/°F or *T*/K as in the original; if necessary, conversions to *T*/K are made, sometimes in the compilations, and always in the critical evaluation. However, the author's units are expressed according to IUPAC recommendations (3) as far as possible.

Errors in calculations, fitting equations, etc. are noted, and where possible corrected. Material inserted by the compiler is identified by the word "compiler" or by the compiler's name in parentheses or in a footnote. Details of smoothing equations (with limits) are included if they are present in the original publication and if the temperature or pressure ranges are wide enough to justify this procedure and if the compiler finds that the equations are consistent with the data.

The precision of the original data is preserved when derived quantities are calculated, if necessary by the inclusion of one additional significant figure. In some cases, compilers note that numerical data have been obtained from published graphs using digitizing techniques. In these

cases, the precision of the data can be determined by the quality of the original graph and the limitations of the digitizing technique.

Method: The apparatus and procedure are mentioned briefly. Abbreviations used in Chemical Abstracts are often used here to save space, reference being made to sources of further detail if these are cited in the original paper. Several reviews on experimental methods of determining gas solubilities are given in (4-10).

Source and Purity of Materials: For each component, referred to as (1), (2), etc., the following information (in this order and in abbreviated form) is provided if available in the original paper: source and specified method of preparation; properties; degree of purity. The solubility is usually more sensitive to impurities in the gaseous component than in the liquid component. However, the most important source of impurities is traces of unwanted gas dissolved in the liquid. Inadequate preliminary degassing of the absorbing liquid is probably the most often overlooked serious source of error in gas solubility measurements.

Estimated Error: If estimated errors were omitted by the original authors, and if relevant information is available, the compilers have attempted to estimate errors (identified by "compiler" or the compiler's name in parentheses or in a footnote) from the internal consistency of data and type of apparatus used. Methods used by the compilers for estimating and reporting errors are based on Ku and Eisenhart (11).

Comments and/or Additional Data: Compilations may include this section, in which short comments relevant to the general nature of the work or additional experimental and thermodynamic data are included which are judged by the compiler to be of value to the reader.

References: The format for these follows the format for the Original Measurements box, except that final page numbers are omitted. References (usually cited in the original paper) are given where relevant to interpretation of the compiled data, or where cross-reference can be made to other compilations.

Evaluations

The evaluator's task is to assess the reliability and quality of the data, to estimate errors where necessary, and to recommend "best" values. The evaluation takes the form of a summary in which all the data supplied by the compiler have been critically reviewed. There are only three boxes on a typical evaluation sheet, and these are described below.

Components: The format is the same as on the Compilation sheets.

Evaluator: Name and affiliation of the evaluator(s); date up to which the literature was checked.

Critical Evaluation:

(a) Critical text. The evaluator checks that the compiled data are correct, assesses their reliability and quality, estimates errors where necessary, and recommends numerical values based on all the published data (including theses, reports and patents) for each given system. Thus, the evaluator reviews the merits or shortcomings of the various data. Only published data are considered. Documented rejection of some published data may occur at this stage, and the corresponding compilations may be removed.

The solubilities in comparatively few systems are known with sufficient accuracy to enable a set of recommended values to be presented, either for measurements near atmospheric pressure or at high pressures. Although many systems have been studied by at least two independent groups of workers, the range of pressures or temperatures is often sufficiently different to make meaningful comparison impossible.

Occasionally, it is not clear why two groups of workers obtained very different but internally consistent sets of results at the same temperature and pressure, although both sets were obtained by reliable methods. In such cases, a decisive assessment may not be possible. In some cases, two or more sets of data have been classified as tentative even though the sets are mutually inconsistent.

Many high pressure solubility data have been published in a smoothed form. Such data are particularly difficult to evaluate, and unless specifically discussed by the authors, the estimated error on such values can be regarded only as an "informed guess".

As well, many high pressure solubility data have been obtained in a more general study of high pressure vapor-liquid equilibrium. In such cases a note is included to indicate that additional vapor-liquid equilibrium data are given in the source. Since the evaluation is for the compiled data, it is possible that the solubility data are given a classification which is better than that which would be given for the complete vapor-liquid data (or vice versa). As an example, it is difficult to

determine coexisting liquid and vapor compositions near the critical point of a mixture using some common experimental techniques which yield accurate high pressure solubility data. As another example, conventional methods of analysis may give results with an expected error which would be regarded as sufficiently small for vapor-liquid equilibrium data but an order of magnitude too large for acceptable high pressure gas-liquid solubility.

Sometimes it is possible to judge the reliability of data for a particular gas-liquid system by testing whether the data are consistent with the behavior of homologous gases or liquids.

(b) Fitting equations. If the use of a smoothing equation is justifiable the evaluator may provide an equation representing the solubility as a function of the variables reported on all the compilation sheets, stating the limits within which it should be used.

(c) Graphical summary. In addition to (b) above, graphical summaries are often given.

(d) Recommended values. Data are recommended if the results of at least two independent groups are available and they are in good agreement, and if the evaluator has no doubt as to the adequacy and reliability of the applied experimental and computational procedures. Data are reported as tentative if only one set of measurements is available, or if the evaluator considers some aspect of the computational or experimental method as mildly undesirable but estimates that it should cause only minor errors. Data are considered as doubtful if the evaluator considers some aspect of the computational or experimental method as undesirable but still considers the data to have some value where the order of magnitude of the solubility is needed. Data determined by an inadequate method or under ill-defined conditions are rejected. However, references to these data are included in the evaluation together with a comment by the evaluator as to the reason for their rejection.

(e) References. All pertinent references are given here, including all those publications appearing in the accompanying compilation sheets and those which, by virtue of their poor precision, have been rejected and not compiled.

(f) Units. While the original data may be reported in the units used by the investigators, the final recommended values are reported in SI units (3) when the data can be accurately converted.

QUANTITIES AND UNITS USED IN COMPILATION AND EVALUATION OF SOLUBILITY DATA

Mixtures, Solutions and Solubilities

A *mixture* (12) describes a gaseous, liquid or solid phase containing more than one substance, where the substances are all treated in the same way.

A *solution* (12) describes a liquid or solid phase containing more than one substance, when for convenience one of the substances, which is called the *solvent*, and may itself be a mixture, is treated differently than the other substances, which are called *solutes*. If the sum of the mole fractions of the solutes is small compared to unity, the solution is called a *dilute solution*.

The *solubility* of a solute 1 (solid, liquid or gas) is the analytical composition of a saturated solution, expressed in terms of the proportion of the designated solute in a designated solvent (13).

"Saturated" implies equilibrium with respect to the processes of dissolution and vaporization; the equilibrium may be stable or metastable. The solubility of a substance in metastable equilibrium is usually greater than that of the same substance in stable equilibrium. (Strictly speaking, it is the activity of the substance in metastable equilibrium that is greater.)

Either point of view, mixture or solution, may be taken in describing solubility. The two points of view find their expression in the reference states used for definition of activities, activity coefficients and osmotic coefficients. Note that the composition of a saturated mixture (or solution) can be described in terms of any suitable set of thermodynamic components.

For gases, the solubility is quoted, where possible, as mole fraction of the saturating gaseous component in the liquid phase at 1 bar partial pressure of gas. The distinction between vapor-liquid equilibria and the solubility of gases in liquids is arbitrary. It is generally accepted that the equilibrium at 300 K between a typical gas such as argon and a liquid such as water is gas liquid solubility whereas the equilibrium between hexane and cyclohexane at 350 K is an example of vapor-liquid equilibrium.

Physicochemical Quantities and Units

Solubilities of gases have been the subject of research for a long time, and have been

expressed in a great many ways, as described below. In each case, specification of the temperature and either partial or total pressure of the saturating gaseous component is necessary. The nomenclature and units follow, where possible, ref. (3). A few quantities follow the ISO standards (14) or the German standard (15); see a review by Cvitaš (16) for details.

A note on nomenclature. In the IUPAC Green Book (3), the solute is component B and the solvent is component A. In compilations and evaluations, the first-named component (component 1) is the solute, and the second (component 2 for a two-component system) is the solvent. The reader should bear these distinctions in nomenclature in mind when comparing equations given here with those in the Green Book.

1. *Mole fraction* of substance 1, x_1 or $x(1)$ (condensed phases) or y_1 (gases):

$$x_1 = n_1 / \sum_{s=1}^c n_s \quad [1]$$

where n_s is the amount of substance of s , and c is the number of distinct substances present (often the number of thermodynamic components in the system). *Mole per cent* of substance 1 is $100 x_1$.

2. *Ionic mole fractions* of salt i , x_{i+} , x_{i-} :

For a mixture of s binary salts i , each of which ionizes completely into v_{s+} cations and v_{s-} anions, with $v_s = v_{s+} + v_{s-}$, and a mixture of p non-electrolytes j , of which some may be solvent components, a generalization of the definition in (17) gives:

$$x_{i+} = \frac{v_{i+} x_i}{1 + \sum_{i=1}^s (v_i - 1) x_i}, \quad x_{i-} = \frac{v_{i-} x_i}{v_{i+}}, \quad i = 1 \dots s \quad [2]$$

$$x'_j = \frac{x_j}{1 + \sum_{i=1}^s (v_i - 1) x_i}, \quad j = (s+1) \dots p \quad [3]$$

The sum of these mole fractions is unity, so that, with $c = s + p$,

$$\sum_{i=1}^s (x_{i+} + x_{i-}) + \sum_{i=s+1}^c x'_i = 1 \quad [4]$$

General conversions to other units in multicomponent systems are complicated. For a three-component system containing non-electrolyte 1, electrolyte 2 and solvent 3,

$$x_1 = \frac{v_{2+} x'_1}{v_{2+} - (v_2 - 1) x_{2+}}, \quad x_2 = \frac{x_{2+}}{v_{2+} - (v_2 - 1) x_{2+}} \quad [5]$$

These relations are used in solubility equations for salts, and for tabulation of salt effects on solubilities of gases (see below).

3. *Mass fraction* of substance 1, w_1 or $w(1)$:

$$w_1 = g_1 / \sum_{s=1}^c g_s \quad [6]$$

where g_s is the mass of substance s . *Mass per cent* of substance 1 is $100 w_1$. The equivalent terms *weight fraction*, *weight per cent* and *g (1)/100 g solution* are no longer used.

4. *Molality* of solute 1 in a solvent 2, m_1 :

$$m_1 = n_1/n_2 M_2 \quad [7]$$

SI base units: mol kg⁻¹. Here, M_2 is the molar mass of the solvent. The equivalent term *weight solubility*, C_w , is no longer used.

5. *Amount concentration* of solute 1 in a solution of volume V , c_1 :

$$c_1 = [\text{formula of solute}] = n_1/V \quad [8]$$

SI base units: mol m⁻³. The symbol c_1 is preferred to [formula of solute], but both are used. The old terms *molarity*, *molar* and *moles per unit volume* are no longer used.

6. *Mass concentration* of solute 1 in a solution of volume V , ρ_1 or γ_1 :

$$\rho_1 = g_1/V \quad [9]$$

SI base units: kg m⁻³.

7. *Mole ratio*, $r_{A,B}$ (dimensionless) (16)

$$r_{A,B} = n_1/n_2 \quad [10]$$

Mass ratio, symbol $\zeta_{A,B}$, may be defined analogously (16).

8. *Ionic strength*, I_m (molality basis), or I_c (concentration basis):

$$I_m = \frac{1}{2} \sum_i m_i z_i^2$$
$$I_c = \frac{1}{2} \sum_i c_i z_i^2 \quad [11]$$

where z_i is the charge number of ion i . While these quantities are not used generally to express solubilities, they are used to express the compositions of non-saturating components. For a single salt i with ions of charges z_+ , z_- ,

$$I_m = |z_+ z_-| \nu m_p, \quad I_c = |z_+ z_-| \nu c_i \quad [12]$$

Mole and mass fractions are appropriate to either the mixture or the solution point of view. The other quantities are appropriate to the solution point of view only. Conversions between some pairs of these quantities can be carried out using the equations given in Table 1 at the end of this Introduction. Other useful quantities will be defined in the prefaces to individual volumes or on specific data sheets.

In addition to these well-defined SI-based units, other units have been used to express the solubilities of gases. Units and nomenclature follow (4, 5, 7, 18), as modified by IUPAC recommendations (3). The equations describing Bunsen, Kuenen, Ostwald and absorption coefficients, as well as Henry's law constants, hold for ideal gases and perfect solutions only. Corrections for non-ideality should be made where possible. The corrections are less than 1 % for most gases near atmospheric pressure (5).

In much published data, the reference pressure is 1 atm = 0.101325 MPa rather than 1 bar = 0.1 MPa.

9. *Bunsen coefficient*, α (dimensionless):

The volume of saturating gas, V_1 , reduced to $T^0 = 273.15$ K, $p^0 = 1$ bar, which is absorbed by unit volume V_2^* of pure solvent at the temperature of measurement and partial pressure $p^0 = 1$ bar. If the gas is ideal, Henry's law (see below) holds, and the liquid is incompressible, then

$$\alpha = \frac{V_1^o}{V_2^*} = \left(\frac{V_1}{V_2^*} \right) \left(\frac{T^o}{T} \right) \quad [13]$$

10. *Kuenen coefficient, S:*

The volume of saturating gas, $V(g)$, reduced to $T^o = 273.15$ K, $p^o = 1$ bar, which is dissolved by unit mass of pure solvent at the temperature of measurement and partial pressure 1 bar. Thus,

$$S = \frac{V_1 T^o}{g_2 T} = \frac{\alpha V_{m,2}}{M_2} \quad [14]$$

SI base units: $\text{m}^3 \text{kg}^{-1}$. Here, M_2 is the molar mass of the solvent. The Kuenen coefficient is proportional to the molality of the dissolved gas.

11. *Ostwald coefficient, L (dimensionless) (18):*

The volume of saturating gas, V_1 , absorbed by a volume V_2^* of pure solvent at the temperature and pressure of the measurement. Thus,

$$L = \frac{V_1}{V_2^*} = \left(\frac{\alpha T}{T^o} \right) \left(\frac{p^o}{p} \right) \quad [15]$$

The Ostwald coefficient is equal to the ratio of the amount concentrations in the gas and in the liquid.

12. *Absorption coefficient, β (dimensionless):*

The most common of several definitions of absorption coefficient is the volume of gas, reduced to $T^o = 273.15$ K, $p^o = 1$ bar absorbed per unit volume of pure solvent at a total pressure of 1 bar. The absorption and Bunsen coefficients are therefore very similar, and are connected by

$$\beta = \alpha(1 - p_2/p^o) \quad [16]$$

where p_2 is the partial pressure of the vapor of the solvent.

13. *Henry's Law constant, k_H :*

$$K_H = \lim_{x_1 \rightarrow 0} \left(\frac{p_1}{x_1} \right) \quad [17]$$

SI base units: Pa. Unfortunately, the definition is used often at finite mole fractions, even though this is a limiting law. The following have also been defined as Henry's Law constants:

$$\begin{aligned} K_2 &= p_1^g/c_1 \\ K_c &= c_1^g/c_1 \end{aligned} \quad [18]$$

where superscript g refers to the gas phase. K_2 has SI base units $\text{Pa m}^3 \text{mol}^{-1}$, and K_c is dimensionless. The Henry's law constant has also been called the Henry coefficient and the Henry constant. Henry's law can be used, with great caution, to convert data from the experimental pressure to 1 bar if the mole fraction of the gas in the liquid is small, and the difference in pressures is small.

The relations between the mole fraction solubility and the various quantities given above are as follows. Note again that these relations hold for ideal gaseous and perfect solution phases only.

$$\begin{aligned}
 x_1 &= \frac{1}{1 + \frac{RT^o}{p_1^o V_{m,2}^* \alpha}} = \frac{1}{1 + \frac{RT^o}{p_1^o M_2 S}} \\
 &= \frac{1}{1 + \frac{RT}{p_1 V_{m,2}^* L}} = \frac{1}{1 + \frac{RT^o}{p^o V_{m,2}^* \beta}}
 \end{aligned}
 \tag{19}$$

14. Salt Effects on the Solubility of Gases (19)

These are often reported as Sechenov (Setchenow, Setschenow) salt effect parameters k_{syz} , which are defined in various ways. The general semi-empirical Sechenov equation is

$$\log(z_1^o/z_1) = k_{syz} y \tag{20}$$

where solubility is expressed in quantities z , with superscript o designating pure solvent, and salt composition is expressed in quantities y . The quantities c_2 , m_2 , x_2' , I_m and I_c are used for y , and the quantities c_1 , m_1 , x_1 , α , S and L for z , giving 30 definitions of k_{syz} . Here, components 1 and 2 are the gaseous solute and electrolyte, respectively. The ratios of z -values are the same for $z = c_1$, α and L and for m_1 and S , respectively, leaving 15 distinct definitions. If z is the same, the definitions of k_{syz} are related simply through 10 equations between pairs of c_2 , m_2 , x_2' , I_m and I_c . Some relations among the definitions, in terms of k_{scc} , k_{smm} and k_{sxx} , are:

$$\begin{aligned}
 k_{scc} &= k_{sca} = k_{scL} = \frac{m_2}{c_2} k_{smc} = \frac{x_2'}{c_2} k_{sxc} = \frac{I_c}{c_2} k_{slc} \\
 k_{smm} &= \frac{x_2'}{m_2} k_{sxm} = k_{smS} = \frac{c_2}{m_2} k_{scm} = \frac{I_m}{m_2} k_{slm} \\
 k_{sxx} &= \frac{c_2}{x_2'} k_{scx} = \frac{m_2}{x_2'} k_{smx} = \frac{I_m}{x_2'} k_{slm} = \frac{I_c}{x_2'} k_{slx}
 \end{aligned}
 \tag{21}$$

These relations hold when a single salt is present; note that the relations between ionic strength and either molality or concentration are simple. If more than one salt is present, the ionic strength is the only practical quantity to be used for y .

Conversions between pairs of k_{scc} , k_{smm} and k_{sxx} are more complicated, and can be found using eqn [5] and Table 1 at the end of this Introduction. For example,

$$k_{sxx} = f(m) \left(\frac{k_{smm}}{v_{2+}} + \frac{1}{m_2} \log \frac{f(m)}{f(m^o)} \right) \tag{22}$$

where

$$f(m) = 1 + (m_1 + v_2 m_2) M_3 \quad f(m^o) = 1 + m_1^o M_3 \tag{23}$$

Errors in the salt effect parameters, as defined above, can be large. If the relative standard deviation in measurement of solubility is $s(c_1)/c_1$, then the relative standard deviation in k_{scc} is

$$\frac{s(k_{scc})}{k_{scc}} = \frac{\sqrt{2}}{c_2 k_{scc} \ln 10} \frac{s(c_1)}{c_1} \tag{24}$$

For example, for $k_{\text{sc}} = 0.1$ and $c_2 = 0.01 \text{ mol dm}^{-3}$, $s(k_{\text{sc}})/k_{\text{sc}}$ is 30 % when $s(c_1)/c_1 = 0.05 \%$ and 1200 % when $s(c_1)/c_1 = 2 \%$. At $c_2 = 1 \text{ mol dm}^{-3}$, the corresponding errors are 0.3 and 12 %, respectively.

If the solubility of a gas is greater than about $x = 0.01$ at partial pressure 1 bar, then several other factors must be taken into account, such as the density of the solution or the partial molar volume of the dissolved gas. In addition, corrections should be made for non-ideality of the gas. See (18) for details.

In addition, the following definitions concerning density are useful in conversions between concentrations and other quantities.

15. *Density*, ρ or γ :

$$\rho = g/V \quad [25]$$

SI base units: kg m^{-3} . Here g is the total mass of the system.

16. *Relative density*, $d = \rho/\rho^0$: the ratio of the density of a mixture at temperature t , pressure p to the density of a reference substance at temperature t' , pressure p' . For liquid solutions, the reference substance is often water at 4°C , 1 bar. (In some cases 1 atm is used instead of 1 bar.) The term *specific gravity* is no longer used.

Thermodynamics of Solubility (20)

Thermodynamic analysis of solubility phenomena provides a rational basis for the construction of functions to represent solubility data, and thus aids in evaluation, and sometimes enables thermodynamic quantities to be extracted. Both these aims are often difficult to achieve because of a lack of experimental or theoretical activity coefficients. Where thermodynamic quantities can be found, they are not evaluated critically, since this task would involve examination of a large body of data that is not directly relevant to solubility. Where possible, procedures for evaluation are based on established thermodynamic methods. Specific procedures used in a particular volume will be described in the Preface to that volume.

Only one thermodynamic result is mentioned here: the temperature dependence of solubility. Sometimes it is possible to fit the mole fraction solubility at various temperatures using the equation

$$\ln x_1 = A + B(K/T) + C \ln(T/K) + D(T/K) \quad [26]$$

where A , B , C and D are constants to be determined from least-squares fitting of the data. Sometimes, to avoid singular matrices of the least-squares normal equations, T is scaled; e.g., T is replaced by $T/100$.

If the gas and the solution of the dissolved gas are ideal, the coefficients can be used to find standard thermodynamic functions for transfer of the gas from the vapor to the liquid phase at the standard pressure (1 bar) and infinitely-dilute dissolved gas, as follows.

$$\Delta G_{m,1}^0/R = -A(T/K) - B - C(T/K) \ln(T/K) - D(T/K)^2 \quad [27]$$

$$\Delta S_{m,1}^0/R = A + C \ln(T/K) + C + 2D(T/K) \quad [28]$$

$$\Delta H_{m,1}^0/R = -B + C(T/K) + D(T/K)^2 \quad [29]$$

$$\Delta C_{m,p}^0/R = C + 2D(T/K) \quad [30]$$

Alternatively (but equivalently), the standard state of infinitely-dilute dissolved gas can be described as a hypothetical ideal dissolved gas at mole fraction $x_1 = 1$, $p = 1$ bar.

PREFACE

The first description of carbon dioxide gas probably dates back to the beginning of the 17th century (1). Jan B. Helmont (1577-1644) found that the gas he had detected in the fumes of a charcoal fire was able to extinguish a lighted candle. He named the gas "*gas sylvestre*" (in Latin *sylvestris*, of a wood). About a hundred years later Joseph Black (1728-1799) studied the gas liberated by heating calcium carbonate (chalk). He gave the gas the name "*fixed air*" since the "air" (gas) was fixed in the solid state in the chalk. In 1772 Joseph Priestley showed that the gas was produced by the burning of charcoal and in 1774 Antoine Laurent Lavoisier proved that it was an oxide of carbon. Lavoisier proposed the name "*carbonic acid*" because of the acidic properties of the gas. In 1854 Auguste Laurent, recognizing that the acid was essentially a solution of the oxide, proposed that the name carbonic acid should be reserved for the solution and that the gas should be called "*carbonic anhydride*". The term *dioxide* for an oxide containing two atoms of oxygen came into use in the middle of the 19th century. (1)

Solubility measurements for carbon dioxide in water date back at least as far as to the work of William Henry (1803) in which he postulated his famous law of solubility. The first accurate solubility data, however, began to appear in about the middle of the 19th century with the pioneering work of Robert Bunsen (1855). Since then, the solubility of carbon dioxide in water and aqueous electrolyte solutions has been the subject of intensive research. For this volume, the scientific literature starting historically with Bunsen's work (1855) has been systematically searched. The coverage should include most articles published up to the end of 1994. In spite of careful search, some published measurements may have been missed. We would appreciate having our attention brought to any important source of data that has been omitted so that we can include it in future volumes.

For many reasons the systems carbon dioxide + water and carbon dioxide + aqueous electrolyte systems are of great importance in our natural environment as well as in physiology, biology, geology, and in many industrial applications - virtually in all branches of science. The solubility of carbon dioxide in water is an order of magnitude larger than that of many other simple gases. Carbon dioxide is one of the naturally occurring atmospheric gases. It is also one of the greenhouse gases which has been increasing steadily in our atmosphere due to human activity. Based on analyses of air trapped in polar ice cores, it is apparent that the average global atmospheric carbon dioxide volume fraction has increased from a pre-industrial level of around 270×10^{-6} to a value of 355×10^{-6} (2).

Water is the most abundant component of the outer layers of the earth and is a constituent of the cells of all plant and animal tissues. It is justifiable to say that the interaction of carbon dioxide and water is a key to the functioning of living organisms. Approximately 97.3 % of the world's vast supply of water is in the oceans. It is estimated that the oceanic carbon dioxide uptake is about 2×10^{15} g of carbon per year (3). The system water + sodium chloride + carbon dioxide is therefore one of the most important fluid systems in geochemistry. On the basis of the literature search done for this volume, the solubility of carbon dioxide in aqueous sodium chloride solutions has been the subject of investigation much more often than the solubility of carbon dioxide in any other aqueous electrolyte solution.

Because of the large number of data, certain systems have been excluded from this volume. For instance, solubility data were not searched for carbon dioxide in some biological fluids such as blood. Beverages like beers, wines and soft drinks have been omitted. Alkaline systems were not included. In this volume the total carbon dioxide dissolved is considered, regardless of the species present in solution. With the higher pressure data there is always a problem of attempting to distinguish between gas solubilities and vapor-liquid equilibria. We have striven to be reasonable in making this distinction. About 85 % of the data sets presented in this volume are at pressures < 200 kPa.

Since 1982 the IUPAC recommendation for the standard pressure, p° , is 10^5 Pa (= 1 bar). Prior to 1982 the standard pressure was usually taken to be $p^\circ = 101\,325$ Pa (= 1 atm, called the *standard atmosphere*). In the majority of the original articles treated in this volume the standard pressure was chosen to be 1 atm. Therefore, the same choice was adopted in this volume. The expression "STP" used in many papers and data sheets of this volume thus means conditions where $p = 101.325$ kPa (= 1 atm) and $T = 273.15$ K ($t = 0$ °C).

In the original articles gas solubilities are presented in an almost bewildering number of units. In the data pages we present the units given in the original papers with explanatory material where necessary. Where it is feasible the compilers have converted these solubilities into the Ostwald coefficient and/or the mole fraction solubility at 101.325 kPa partial pressure of gas. These conversions were carried out for the convenience of the user, and such compiler-generated conversions are noted on the data sheets.

The molar volume of carbon dioxide gas differs from that of an ideal gas. The extent of the deviation is customarily expressed in terms of the second virial coefficient B_{22} . The second virial coefficient for carbon dioxide varies smoothly with temperature, as shown in Figure 1. The values used in the plot of B_{22} vs. T are those of Angus *et al.* and were taken from Dymond and Smith (4).

Figure 1. Variation of the second virial coefficient of carbon dioxide with temperature.

The value of the molar volume, V_m , is given by:

$$V_m = \frac{1}{2}(RT/p) + \frac{1}{2}[(RT/p)^2 + 4B_{22}(RT/p)]^{1/2} \quad (1)$$

At 273.15 K $B_{22} = -151.4 \text{ cm}^3 \text{ mol}^{-1}$ and at 298.15 K $B_{22} = -125.5 \text{ cm}^3 \text{ mol}^{-1}$ (4). Using equation (1) for calculation of the molar volume of carbon dioxide the values presented in Table 1 are obtained at $p(\text{CO}_2) = 101.325 \text{ kPa}$. V_m values from the ideal gas equation are also listed in the table.

Table 1.

T/K	$10^3 V_m / \text{m}^3 \text{ mol}^{-1}$ (eq. 1)	$10^3 V_m / \text{m}^3 \text{ mol}^{-1}$ (id.)
273.15	22.262	22.414
298.15	24.340	24.466

The magnitude of the deviation from ideality is relatively small, but not negligible. The compilers have used, as far as possible, the real gas molar volumes in the conversions.

For the solubility of carbon dioxide in water, recommended equations and tables of values are presented. However, for systems which contain water and electrolytes, the experimental gas solubility in water from that paper is given, even when it is at variance with our recommended value. These data of sometimes poorer quality are presented because the author's ratio of gas solubility in water to solubility in the aqueous solution may be more accurate than the solubility itself.

As the title page shows, this volume is the product of the efforts of a number of people: contributors, members of the Editorial Board past and present, and other members of the IUPAC Commission V.8. I wish to acknowledge their combined contributions and to thank them all.

I wish to express my special thanks to Professor Rubin Battino for his continuously inspiring encouragement during this project and for many helpful discussions as well as constructive criticism. Acknowledgment is made to Professor H. Lawrence Clever, Dr Peter G.T. Fogg and Professor John W. Lorimer for their useful comments and suggestions and for reading critically separate sections of this volume. I am indebted to Dr Rosa Crovetto who did most of the literature search prior to 1988 and to Dr Adam Skrzecz who did part of the word processing for the data sheets prior to 1992. I would also like to thank Miss Xhiao-hui Shen for her assistance in translating Chinese papers. Grateful acknowledgment is made to the *Foundation of Turku University*, *Acta Chemica Scandinavica* and the *Academy of Finland* for the travel grants which enabled me to participate in the annual meetings of the IUPAC Commission V.8. Finally, I wish to express my sincere thanks to Professor Kalevi Pihlaja, the present head of the Chemistry Department of the University of Turku, who has supported this project by providing the computer and other facilities needed for the completion of this work.

CRITICAL EVALUATION:
The Solubility of Carbon Dioxide in Water at Low Pressure.

Measurements of the solubility of carbon dioxide in water date back to at least the beginning of the nineteenth century. However, the first accurate measurements to appear are those of Bunsen (1). Since that time there have been over 75 investigations of the solubility of CO₂ in water at low pressure.

Carroll *et al.* (2) reviewed all of the solubility data for CO₂ in water for pressures below 1 MPa and for temperatures from 273 to 433 K (0 °C to 160 °C). They developed a model for calculating the solubility of CO₂ in water over this range of pressure and temperature using a Henry's law approach.

Most of the papers used in the review of Carroll *et al.* (2) are evaluated later in this volume. However, a few papers report values which Carroll *et al.* (2) concluded were accurate, but contain only one or two points. Thus, it was concluded that they did not warrant a thorough evaluation; however, they did deserve some mention. They are: Just (3), Christoff (4), von Hammel (5), Essery and Gane (6), Bartholomé and Friz (7), Enders *et al.* (8) and Davies *et al.* (9).

The model of Carroll *et al.* (2) was used to calculate the solubility of water when the CO₂ -partial pressure was equal to 101.325 kPa (1 atm). That is, the product of the mole fraction of CO₂ in the vapor and the total pressure ($y_1 \times P$) equals 101.325 kPa. These values are tabulated in Table 1 (next page) and plotted on Fig. 1. The values of the solubilities were then regressed to obtain the following correlation:

$$\ln x_1 = -32.5247 + 0.96017 \tau + 68.0319/\tau + 12.1522 \ln \tau \quad (1)$$

where x_1 is the mole fraction of carbon dioxide in the liquid at a partial pressure of 1 atm, and $\tau = T/100$ where T is in K. This equation is valid for temperatures between 273 and 433 K (0 °C and 160 °C). The average absolute deviation between the model and Eq. (1) is 6×10^{-5} mol %. Values based on the correlation are also included in Table 1. From Table 1 and Fig. 1 it can be seen that the solubility, as defined here, becomes a weak function of the temperature for temperatures greater than about 373 K. In fact the solubility shows a shallow minimum at about 421 K.

The solubilities calculated using the model of Carroll *et al.* (2) were then converted to Ostwald coefficients (volume of gas per unit volume of solvent, both at the specified temperature). For this conversion the density of carbon dioxide was calculated using the truncated virial equation. Second virial coefficients were taken from Angus *et al.* (10). The density of water was taken from *The Steam Tables* (11). The Ostwald coefficients are also listed in Table 1. The average difference between the Ostwald coefficients listed in Table 1 and those that would be obtained by assuming that CO₂ is an ideal gas is 0.33 % and the maximum error is 0.68 %.

It is interesting to note that the minimum solubility, when expressed in Ostwald coefficients, occurs at about 408 K (0.300 cm³ CO₂ / 1 cm³ H₂O). The difference in the location of the minima for the two solubility units is largely due to the fact that the density of water is a function of temperature.

Using the procedure of Wilhelm *et al.* (12), the change in enthalpy, entropy and heat capacity for solution were derived from Eq. (1). These values are included in Table 1 as well. The minimum in the solubility noted above is the point where the calculated enthalpy change on solution is zero. The change in the sign of the enthalpy

change on solution more clearly reveals the minimum solubility than the solubility values themselves. From Table 1 it can be seen that mole fraction solubilities at temperatures from 413 K to 428 K are 1.72×10^{-5} (to three significant figures) whereas the enthalpy change on solution clearly changes sign around 421 K. Finally, this approach predicts that the ΔC_p is a linear function of temperature with $(\partial[\Delta C_p]/\partial T) = 0.08 \text{ kJ mol}^{-1} \text{ K}^{-2}$.

The effect of pressure on the solubility of CO_2 is shown in Fig. 2. The curves on this figure were calculated using the model of Carroll *et al.* (2). A few data points from the literature are plotted on this figure.

CRITICAL EVALUATION:
Evaluation of Solubility Data of the System CO₂-H₂O from 273 K to the Critical Point of Water

This evaluation covers all of the literature sources for the solubility of carbon dioxide in water through the year 1989.

For describing the two-phase saturation solubility we select Henry's constant. From the equality of the chemical potentials of the solute in the vapor and liquid phase, Henry's constant k_H^0 can be calculated from [see O'Connell (1) and Alvarez *et al.* (2)]

$$k_H^0 = (yP\phi_1/\gamma_1^H x) \exp \int_{P_2^*}^P (-V_1/RT)dP. \quad (1)$$

From the equality of the chemical potentials of the solvent in the liquid and the vapor phase it follows that

$$(1-y) = [\gamma_2^R(1-x)P_2^*\phi_2^* \exp \int_{P_2^*}^P (V_2^*/RT)dP]/(P\phi_2) \quad (2)$$

where the symbols are defined at the end of this evaluation. To calculate k_H^0 from the experimental data usually available, namely P , T and x , equations (1) and (2) must be solved simultaneously. The common assumptions for low temperatures and low total pressures and concentrations are that the activity coefficients γ_1^H and γ_2^R equal unity, and that the partial molar volume, V_1 equals the infinite dilution partial molar volume, V_1^0 independent of pressure. Once an equation of state (EOS) is selected, eq. (2) is solved for y by an iterative procedure described elsewhere (3). The explicit pressure dependence of the solubility can be accounted for either by using information on experimental partial molar volumes or by semiempirical perturbation methods (4). For this system experimental partial molar volumes (5,6) were used.

The virial EOS through the second virial coefficient was used for the mixed vapor phase for temperatures between 273 and 353 K. For the higher temperatures, 353 K to the critical temperature of the solvent, the Peng and Robinson (7) EOS was selected. The interaction parameter was chosen as 0.285. [For details on the sensitivity of the Henry's constant to different EOS, smoothing equation selection, and adjustment procedures, see Crovetto (8).] Up to about 500 K all of the EOS tested gave variations of about 1.5 % or less in the calculated values of k_H^0 .

Another useful quantity in solubility and liquid/vapor equilibria is the isothermal distribution coefficient, K_D , defined as

$$K_D = y/x \quad (3)$$

The infinite-dilution coefficient, K_D^0 , is defined as

$$K_D^0 = \lim_{x \rightarrow 0} y/x \quad (4)$$

and can be calculated from the same set of equations and assumptions already presented as

$$K_D^0 = k_H^0/(P_2^*\phi_1^0) \quad (5)$$

where ϕ_1^0 is calculated from the selected EOS. In principle, K_D^0 will be known with the same precision as k_H^0 , but the effect of the selected EOS on the values of K_D^0 and k_H^0 , respectively, will be different.

Recently, Japas and Levelt Sengers (9) predicted the limiting asymptotic thermodynamic behavior for k_H^0 and K_D^0 and their temperature dependence near the critical temperature of the solvent. They demonstrated that asymptotically as $T \rightarrow T_c$ of the solvent, the following linear correlations will apply:

$$T \ln(k_H^0/f_2^*) = A + B(\rho_2^{Hq} - \rho_{c2}) \quad (6)$$

$$T \ln K_D^0 = 2B(\rho_2^{Hq} - \rho_{c2}) \quad (7)$$

$$\text{where } B(R\rho_c^2) = (\partial P/\partial x)_{v,T_c} \equiv -a_{v,x}^c$$

The quantity $a_{v,x}^c$ is the second derivative of the Helmholtz energy with respect to the volume and the concentration. This relevant derivative can be related to the experimentally measurable initial critical-line slopes of the dilute solution and the pure solvent [see Japas and Levelt Sengers (9)]. The fact that K_D^0 must equal unity for $T = T_c$, provides a valuable clue to whether the asymptotic behavior has been reached.

As stated by Harvey *et al.* (10), when dealing with experimental data the K_D^0 factor, eq. (7), gives a better estimate of the true asymptotic slope and a good agreement with the $a_{v,x}^c$ from experimental critical-line data whereas the slope from the Henry's constant, eq. (6), does not.

It is a fact that the hydration and dissociation of CO_2 in water cannot be separated from its dissolution. In this treatment only the total CO_2 dissolved is considered, regardless of the species present in solution. This assumption can be made because any species other than $\text{CO}_2(\text{aq})$ [the not yet isolated, so-called "carbonic acid" (H_2CO_3)_{aq}, the H^+ , and the HCO_3^-] in a solution of CO_2 in water exist in negligible amounts. These species can be ignored because the ratio of the molalities of " H_2CO_3 "_{aq} and ions to CO_2 is about 3/1000 at 298.15 K (11). Also, experimental and theoretical arguments of Kruse and Franck (12) indicate that (H_2CO_3)_{aq} is not an important species at higher temperatures. The acidity constant of CO_2 goes through a maximum value of 6.3×10^{-7} mol kg^{-1} at 353 K and decreases at higher temperatures (13,14), so that the quantity of ionic species should become smaller as the temperature increases beyond 353 K.

Wherever necessary, values for the pure water properties, ρ , f_2^* , P_2^* were taken from Haar *et al.* (15).

The goal of this evaluation was to cover with one equation the solubility of CO_2 in water for the liquid range of water 273 to 647.126 K. This was not possible within the precision of the available measurements. The data for low temperature solubilities, 273 to 353 K, are always significantly more precise, i.e., at least by a factor of ten than the high temperature ones. For this system there are no data at low temperatures of very high precision similar to those available for inert non-polar gases in water (16, 17).

At the present time equations for the temperature dependence of gas solubilities in water are only empirical showing limiting asymptotic critical behavior and tendencies (9). The parameters for this equation (9) must be adjusted from the data.

The original data were retrieved as mole fraction, total pressure in the system, and temperature. From these data, the selected EOS, and equations (1) and (2), k_H^0 was calculated. For the low temperature data set (273 - 353 K), the equation is

$$\ln(k_H^0/\text{bar}) = 4.800 + 3934.4(T/K)^{-1} - 941290.2(T/K)^{-2} \quad (8)$$

The standard deviation of the fit is 1.1 % in k_H^0 . The coefficients were calculated by a least squares method. A further increase in the number of coefficients in eq. (8) was not statistically significant. The references used for eq. (8) are listed alphabetically in Table 1, entitled "Sources of data". For the low-temperature set, the correction for non-ideality of the vapor phase does not amount more than 0.5 %.

There is available a low-temperature low-pressure evaluation for the carbon dioxide/water system done by Wilhelm *et al.* (18). They made different choices for the number of sources considered and the smoothing equation used. Differences between k_H^0 values calculated from eq. (8) and theirs are important only at the end of the temperature interval of the fitting, i.e., at 273 and 353 K, amounting to 2 % at 353 K.

Any formulation that attempts to cover the entire liquid range of the solvent should be consistent with the facts that the derivative $[d(\ln k_H^0)/dT]_s$ diverges to $-\infty$ as $T \rightarrow T_c$ [Japas and Levelt Sengers (9)], that the infinite dilution solute partial molar isobaric heat capacity of dissolution in the saturated liquid, C_{pi}^0 , diverges to $+\infty$ as $T \rightarrow T_c$, and that the value of k_H^0 at T_c is a constant equal to P_2^* times ϕ_1^0 .

For the high-temperature data set, 353 K to the critical temperature of water, the system was anchored at the low temperature by adding to the sources used five k_H^0 values calculated from eq. (8) at 273.15, 293.15, 303.15, 323.15 and 353.15 K. They were given the same weight as any other experimental points. However, they were not used for eq. (7). For the $\text{CO}_2/\text{H}_2\text{O}$ system the linear relationship in eq. (7) is obtained starting at densities which correspond to about 373 K.

The high-temperature data set is best represented in K_D^0 by

$$T \ln K_D^0 = 91.22 \text{ K}(\text{mol/L})^{-1} (\rho_2^{\text{H}_2\text{O}} - \rho_{c2}) \quad (9)$$

which gave a standard deviation of 8.6 % (in Henry's constant), and in k_H^0 by

$$\ln(k_H^0/\text{bar}) = 1713.53(1-T_r)^{1/3}(T/\text{K})^{-1} + 3.875 + 3680.09(T/\text{K})^{-1} - 1198506.1(T/\text{K})^{-2} \quad (10)$$

with a standard deviation of 5.1 % in k_H^0 . In eq. (10) $T_r = T/T_c$. The asymptotic leading term is adjusted by the results obtained from fitting the data to the form of eq. (7). Coefficients for eq. (10) were obtained from a least squares procedure with no weighting applied. The list of sources used is given in Table 1.

A group of sources exist that are at low temperatures, but higher pressures. This group consists of eight different sources and is listed alphabetically in Table 1. From the experimental data, 23 values of Henry's constant were calculated at different temperatures. This group was difficult to evaluate because for some experimental conditions CO_2 itself is very near its critical point. This group was not included in the fitting.

For this system we estimate an uncertainty in the fitting equations of 1 % for k_H^0 between 273 and 353 K, and an uncertainty of about 5-10 % between 353 and 600 K. For temperatures above 600 K the uncertainty increases rapidly to at least 20 % near the critical point of water.

A high-temperature deviation plot versus temperature shows that there may be some systematic errors between experimental data from different sources.

Smoothed values for $\ln(k_H^0/\text{bar})$ calculated from eq. (8), at 10 K intervals between 273 and 353 K are given in Table 2.

Smoothed values for $\ln(k_H^0/\text{bar})$ between 353 and 647 K at 15 K intervals calculated from equations (9) and (10) are given in Table 3.

Recommended values for k_H^0 calculated from the selected fitting equation (8), considering all sources, at 5 K intervals from 273.15 to 353.15 K are given in Table 4.

List of symbols

$a_{v,x}$	second derivative with respect to the volume and composition of the Helmholtz energy
k_H	Henry's constant
x	mole fraction of solute in the liquid phase
y	mole fraction of solute in the vapor phase
f	fugacity
$C_{p,1}$	partial molar isobaric heat capacity for the solute
K_D	isothermal distribution coefficient
P	total pressure
R	gas constant
T	temperature
T_c	critical temperature of the solvent
$T_r = T/T_c$	reduced temperature
V	molar volume
V_i	partial molar volume of i

Greek symbols:

ρ	molar density
ϕ_i	fugacity coefficient in the gaseous mixture of component i
γ^H	activity coefficient in the liquid phase on the scale defining ideality by means of Henry's law
γ^R	activity coefficient in the liquid phase on the scale defining ideality by means of pure solvent behavior or Raoult's law

Subscripts: 1: solute, 2: solvent, c: critical

Superscripts: 0: infinite dilution, *: pure substance, g: vapor phase, liq: liquid phase, s: saturation, c: critical

The meaning of the symbols used in the table follows:

For Group A: The numbers in parenthesis, (m:n), are $m =$ the number of experimental points given in the source, and $n =$ the number of points actually considered in the evaluation.

For Groups B and C: i: several isothermal solubility measurements are available for different pressures. When feasible, a graphical extrapolation for Henry's constant, k_H , to the solvent vapor pressure was performed. The numbers in parenthesis, (m:n), are $m =$ the number of k_H^0 's obtainable from the source, $n =$ the number actually considered.

ii: only one pressure, or a very small pressure range, was experimentally studied in the source. The numbers in parenthesis, (m:n), are in this case $m =$ the number of experimental points informed, $n =$ the number of points considered in the evaluation. The experimental partial molar volume of the solute is considered for calculating k_H^0 in eq. (1).

In Group C the range of T and P of the measurements is given. In Group B, only the range of P is given.

There are also compiled data sources which were not used in the evaluation: (1) Setchenov, J. [Sechenov, I.M.] *Pflügers Arch. Gesamte Physiol. Menschen Tiere* **1874**, *8*, 1-39; *Mem. Acad. Imp. <p>AUXILIARY INFORMATION</p>																															
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Apparently generated from limestone and sulfuric acid. Dried.</p> <p>(2) Not specified, assumed to be distilled.</p> <p>ESTIMATED ERROR:</p> <p>The author makes a qualitative statement that the results are good to the second decimal.</p> <p>REFERENCES:</p> <p>1. AUXILIARY INFORMATION																																																																																																	
METHOD/APPARATUS/PROCEDURE: An all-glass apparatus was used. The gas was bubbled through water kept in a constant temperature bath until equilibrium was reached. After equilibration a liquid sample was volumetrically analyzed for its CO ₂ content. The volume of the solution was pycnometrically determined at the temperature of the measurement.	SOURCE AND PURITY OF MATERIALS: (1) Not stated. (2) Not stated.																																																																																																
ESTIMATED ERROR: 1 % in S . (By the author.)

<p>AUXILIARY INFORMATION</p>													
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The authors were concerned that too vigorous shaking might lead to supersaturation because of local pressure differences. They designed four versions of an apparatus in which the gas and solvent would be contacted at atmospheric pressure only.</p> <p>In the final version the gas is circulated through the degassed solvent in an all-glass apparatus by a pumping system of mercury reservoirs and bulbs activated by a rocking beam.</p> <p>The solvent was degassed by boiling under reduced pressure for one hour.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Prepared by the action of sulfuric acid on an aqueous solution of sodium bicarbonate. The gas was passed through several wash bottles containing distilled water.</p> <p>(2) Distilled.</p> <p>ESTIMATED ERROR:</p> <p>$\delta L/L = \pm 0.005$ (compiler)</p> <p>REFERENCES:</p>

^a Calculated by the compiler. ^b Bunsen coefficient [cm ³ (STP) cm ⁻³ atm ⁻¹].					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: A "conventional" high-pressure apparatus was used. Equilibrium in the system was attained by bubbling gas at constant pressure. The equilibrium composition in the system was determined by measuring the volume of water, and the pressure and volume of the dissolved CO ₂ in a buret that was thermostatted. The solubilities of the gas mixtures CO ₂ -H ₂ were also measured with the same experimental apparatus. Details are given in the source. The authors calculated the fugacity of the pure gas from Ref. 1.		SOURCE AND PURITY OF MATERIALS: Nothing specified.			
		ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta P/\text{kg cm}^{-2} = \pm 0.1$

^a Calculated by the compiler. ^b S_1 = solubility of CO ₂ in water [cm ³ (STP) cm ⁻³]							
AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE:				SOURCE AND PURITY OF MATERIALS:			
The saturation of water with CO ₂ was achieved in a thermostatted rocking autoclave with inner walls plated with silver. CO ₂ solubility was determined by measuring the volume of the gas desorbed from the solution under ambient conditions. The equipment was similar to that used in Ref. 1.				Nothing specified.			
				ESTIMATED ERROR:			
				Nothing specified.

^a Calculated by the compiler. ^b Solubility of CO ₂ (cm ³ at STP per gram of water).							
Authors' note: There is a change in solubility vs pressure in the low temperature range and at 100-200 atm that could suggest the coexistence of two liquid phases.							
AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE: A high-pressure autoclave was used. Two flasks helped to maintain pressure constant during sampling. Pressure was read on a dead weight gauge. The liquid sample was analyzed for its CO ₂ content by expansion into a thermostatted gas buret. It was not stated if stirring was used.			SOURCE AND PURITY OF MATERIALS: (1) Purity 99.98 %. (2) Not stated.				
			ESTIMATED ERROR: Not given.

AUXILIARY INFORMATION																																																																																																					
METHOD/APPARATUS/PROCEDURE: The apparatus used was the same high pressure autoclave as in Ref. 1. After equilibration, samples were taken from the gas phase. No pressure stability was provided during sampling. The authors could not discard completely the possibility of spray formation in the sampling procedure. The samples were analyzed by weighing. For CO ₂ , $T_c = 304.20$ K (31.05 °C) $P_c = 72.8$ atm	SOURCE AND PURITY OF MATERIALS: (1) Not stated. (2) Not stated. ESTIMATED ERROR: REFERENCES: 1. Wiebe, R.; Gaddy, V. L. <i>J. Am. Chem. Soc.</i> <u>1939</u> , 61, 315-8.

AUXILIARY INFORMATION																																																																																											
METHOD/APPARATUS/PROCEDURE: The same apparatus and method were used for measurements of solubility and electromotive force. A detailed description of the experimental procedure is available in the source. Equilibrium in the cell was attained by bubbling CO ₂ through the solvent while gently rocking the thermostatted cell. Pressure was maintained constant at 1 atm. The concentration was determined by titrating about 90 cm ³ of solution with excess standard Ba(OH) ₂ solution and back-titrating the excess.	SOURCE AND PURITY OF MATERIALS: (1) From commercial tank. Purity 99.67 % ± 0.05 %. (2) Quality not stated. Degassed by CO ₂ bubbling and evacuation. ESTIMATED ERROR: $\delta S = \pm 0.2 \%$ (By authors) REFERENCES:

AUXILIARY INFORMATION																																																																																																																									
METHOD/APPARATUS/PROCEDURE: An improved apparatus for solvent pretreatment was used (Ref. 1). The gas content in the solution was analyzed with a gas burette. The solvent was equilibrated by flowing a liquid film through the gas. No supersaturation was observed.	SOURCE AND PURITY OF MATERIALS: (1) Prepared from marble. The system was sealed to prevent contamination with air. (2) Pure. Degassed.																																																																																																																								
ESTIMATED ERROR: Not stated.

AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE:				SOURCE AND PURITY OF MATERIALS:			
Static bomb of approximately 100 cm ³ capacity. Heated in electric tube furnace. Liquid volume of approximately half to two thirds bomb volume. Samples of mixture analysed by absorbing water in Anhydrone and carbon dioxide in carbosorb. Details in source.				Carbon dioxide generated in apparatus by reaction of sodium bicarbonate and hydrochloric acid.			
				Two series studied:			
				Series A: 0.02 moles NaHCO ₃ ; 0.00797 moles HCl; 42 or 52 cm ³ of water. Series B: 0.007 moles NaHCO ₃ ; 0.00302 moles HCl; 55 cm ³ of water.			
				ESTIMATED ERROR: δT/K = ± 2.0; δx ₁ = ± 4 % (estimated compiler).

AUXILIARY INFORMATION																																																	
METHOD/APPARATUS/PROCEDURE: A two liter, 316 stainless steel stirred reactor was used. Water was degassed "in situ". The concentration of the gas in the liquid was determined by desorption from a known volume of liquid followed by volumetric analysis of the evolved gas. Equilibration times were of the order of five hours at 150 °C and above.	SOURCE AND PURITY OF MATERIALS: (1) 99.5 %. (2) Demineralized.																																																
ESTIMATED ERROR: In Henry's constant 5.8 % (by author). (Detailed analysis of experimental contributions to the total error is given in the source.)

AUXILIARY INFORMATION																																							
METHOD/APPARATUS/PROCEDURE: <p>The solubility was measured in a glass vessel which was filled with a calibrated volume of solvent. The solvent was degassed, and the vapor-liquid equilibrium was established. Equilibrium pressure was recorded by a pressure transducer. The gas was fed to the vessel until an arbitrary pressure ($P \leq 10^5$ Pa) was reached. The pressure was recorded again. The vessel was closed, and the magnetic stirrer was started to agitate the liquid. After the equilibrium pressure was reached the solubility was calculated, based on Henry's law.</p> <p>In the paper the authors report solubility and diffusivity of CO₂ and N₂O in water and aqueous alkanolamine solutions.</p>	SOURCE AND PURITY OF MATERIALS: (1) Nothing specified. (2) Distilled. Degassed.																																						
ESTIMATED ERROR: The reproducibility between the various experiments was within 3 %.

AUXILIARY INFORMATION																					
METHOD/APPARATUS/PROCEDURE: Static-state method. The authors designed a solubility apparatus which is composed of three isothermal pre-saturators, saturator and sampler. A schematic diagram of the apparatus is in the original source. CO ₂ was introduced (10 hours) through the pre-saturators and the saturator which contained about 120 g of solvent. The equilibrated sample (about 100 g) was transferred from the saturator into the weighed sampler which contained a weighed amount of standard NaOH solution. The sampler was weighed again and shaken to complete the reaction between CO ₂ and NaOH. The excess of NaOH and the NaHCO ₃ was titrated potentiometrically with standard HCl solution. The mass of dissolved CO ₂ was calculated from the equation $w = c_{HCl}(V_2 - V_1)M$ where w = mass of dissolved CO ₂ , c _{HCl} = concentration of HCl; V ₁ and V ₂ are volumes of the HCl solution to the first and second end point, respectively, and M = molar mass of CO ₂ . (The authors also report solubilities of CO ₂ in 15 mass % glucose/H ₂ O and in NaCl + 15 mass % glucose/H ₂ O.)	SOURCE AND PURITY OF MATERIALS: (1) Purity of CO ₂ 99.95 %. (2) Double deionized. Conductivity of H ₂ O was < 1.5×10 ⁻⁴ S m ⁻¹ ESTIMATED ERROR: $\delta T/K = \pm 0.02$ When fitting the data to the equation $\lg S_1 = A/T + B + CT$, the standard deviation was σ = 0.02. (Table 2.)																				

COMPONENTS: (1) Carbon dioxide; CO ₂ ; [124-38-9] (2) Water-d ₂ ; D ₂ O; [7789-20-0] (3) Water; H ₂ O; [7732-18-5]	EVALUATOR: Pirketta Scharlin Department of Chemistry University of Turku FIN-20500, Turku, Finland August 1995

CRITICAL EVALUATION:
The Solubility of Carbon Dioxide in D₂O and in Mixtures of D₂O and H₂O.

The system CO₂-D₂O has not been studied by many workers. The first solubility measurements were made by Curry and Hazelton (1) in 1938, a few years after the discovery of deuterium. Since then only three research groups have reported solubility data for CO₂ in heavy water. Salomaa *et al.* (3) measured the solubility of CO₂ in pure H₂O, pure D₂O and in mixtures of H₂O and D₂O at 298.15 K and atmospheric pressure using the same method as Curry and Hazelton. Kratochvil *et al.* (5) report solubility values in pure D₂O at three temperatures (303.15, 323.15, and 353.15 K) and partial pressures of CO₂ between 55 and 3972 kPa. The data from references (1), (3) and (5) are used in this evaluation. At high temperatures and pressures there exists one set of measurements by Kapitanov *et al.* (6). Unfortunately, there is not enough information in Kapitanov's paper for the calculation of mole fraction solubilities, and these data will not be handled further in this evaluation.

To represent the temperature dependence of the mole fraction solubility of CO₂ in D₂O at 101.325 kPa partial pressure of gas the data from references (1), (3) and (5) were fitted to equation 1.

$$\ln x_1 = A + B / (T/100 \text{ K}) + C \ln(T/100 \text{ K}) \quad (1)$$

The best fit for the five points in the temperature range 298 - 353 K gave equation 2,

$$\ln x_1 = -34.0577 + 49.6909 / (T/100 \text{ K}) + 9.1455 \ln(T/100 \text{ K}) \quad (2)$$

where x_1 is the mole fraction solubility of CO₂ at 101.325 kPa partial pressure of gas. The fit in $\ln x_1$ gave a standard deviation of 1.1 %. Smoothed values of the mole fraction solubility and changes in the thermodynamic functions on solution are shown in Table 1 at 5 K intervals. The thermodynamic properties were calculated from the smoothing equation according to the following equations:

$$\Delta S_1^\circ = R [A + C \ln(T/100 \text{ K}) + C] \quad (3)$$

$$\Delta H_1^\circ = R (-100B + CT) \quad (4)$$

Table 1. Smoothed values of the solubility of carbon dioxide in water-d₂, and thermodynamic functions^a at 5 K intervals using equation 2 at 101.325 kPa partial pressure of gas.

T/K	10 ³ x ₁	ΔH ₁ ^o /kJ mol ⁻¹	ΔS ₁ ^o /J K ⁻¹ mol ⁻¹

348.15	0.230	-14.8	112
353.15	0.214	-14.5	111

^a For the calculation of ΔC_{p,1}^o an equation ΔC_{p,1}^o = RC can be derived from equation 1. This gives a value of 76 J K⁻¹ mol⁻¹ for ΔC_{p,1}^o.

Figure 1 shows the temperature dependence of the mole fraction solubility for carbon dioxide in D_2O at 101.325 kPa partial pressure of gas. The curve was obtained from the smoothing equation 2. For comparison, the temperature dependence of the mole fraction solubility for CO_2 in H_2O is presented in the same figure as a dotted curve which was obtained from the smoothing equation given by Carroll and Mather in the CO_2 - H_2O section of this volume ("The Solubility of Carbon Dioxide in Water at Low Pressure", Eq. (1)).

Figure 1. Mole fraction solubility of carbon dioxide in D_2O at 298.15 to 353.15 K and 101.325 kPa partial pressure of gas. For comparison, the mole fraction solubility of CO_2 in H_2O in the same temperature interval is presented as the dotted curve.

In Figure 2 the pressure dependence of the mole fraction solubility of carbon dioxide in D_2O at three different temperatures is presented.

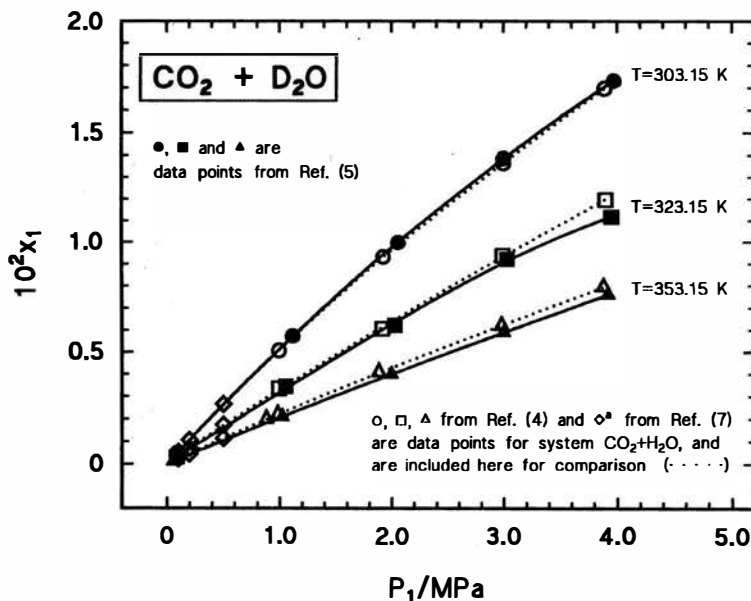

Figure 2. Mole fraction solubility of CO_2 vs. partial pressure of CO_2 at different temperatures. Data points \diamond are from calculated values obtained using the model outlined in Ref. (7).

The only reported data for the solubility of CO₂ in mixtures of D₂O and H₂O are the data of Salomaa *et al.* (3). In the original paper the Ostwald coefficients are given. To calculate the molality of CO₂ in mixed solutions the H₂O-D₂O density data are needed. Salomaa has unpublished density data which are worth publishing in this connection. In his measurements, Salomaa used the procedure described by Kirshenbaum (2). The values for the density of L₂O (L = H,D) at 298.15 K are listed in Table 2.

Table 2. Density of H₂O-D₂O mixtures at 298.15 K.

$x(\text{D};\text{L}_2\text{O})^a$	$\rho(\text{L}_2\text{O})/\text{g cm}^{-3}$ (L = H,D)
0.4524	1.045974
0.4695	1.048081
0.6156	1.063921
0.9373	1.098754
0.9399	1.099030
0.9881	1.104246
0.9980	1.105312

^a $x(\text{D};\text{L}_2\text{O})$ = deuterium isotope mole fraction of water, (L = H,D)

By the method of least squares equation (5) is obtained from the data of Table 2. The linear correlation between $\rho(\text{L}_2\text{O})$ and $x(\text{D};\text{L}_2\text{O})$ is excellent (correlation coefficient $r = 0.999995$), and at $x(\text{D};\text{L}_2\text{O}) = 0$ the density values extrapolate well to the density of pure H₂O at 298.15 K, as they should.

$$\rho(\text{L}_2\text{O})/\text{g cm}^{-3} = (0.10852 \pm 0.00015) \times x(\text{D};\text{L}_2\text{O}) + (0.99704 \pm 0.00012) \quad (5)$$

Using a real gas molar volume of 24.34 dm³ mol⁻¹ and the L₂O densities obtained from equation (5), the evaluator calculated the molalities of CO₂ in the mixtures of H₂O and D₂O from the Ostwald coefficients given in (3). In Figure 3 the molality of CO₂ at 298.15 K and 101.325 kPa partial pressure of CO₂ is presented as a function of the deuterium isotope mole fraction $x(\text{D};\text{L}_2\text{O})$ in the solvent water.

Figure 3. Molality of CO₂ vs. the deuterium isotope mole fraction of solvent water.

Comparison of the smoothed mole fraction solubilities of CO₂ in D₂O (from Table 1) with corresponding solubilities of CO₂ in H₂O (Carroll & Mather, CO₂-H₂O section, "The Solubility of Carbon Dioxide in Water at Low Pressure", Table 1, Equation (1)) shows that between 298.15 and 323.15 K the solubility of CO₂ in D₂O is 1.5 - 2 % lower than the solubility of CO₂ in H₂O. The difference increases with increasing temperature, and at 353.15 K the mole fraction solubility of CO₂ in D₂O is about 9 % lower than in H₂O (see also Fig. 1). This differs from most simple nonpolar gases for which the mole fraction solubility in D₂O is higher than in H₂O by about 5 - 15 % at 288.15 to 318.15 K and 101.325 kPa partial pressure of gas (8, 9).

The experimental values of Kratochvil *et al.* (5) predict a higher value for the solubility of CO₂ in D₂O at 298.15 K and 101.325 kPa than the value for the solubility of CO₂ in H₂O. However, the two independent measurements (1, 3) at 298.15 K and 101.325 kPa, which are in good agreement with each other, support the value of $x_1 = 0.611 \cdot 10^{-3}$ for the solubility of CO₂ in D₂O, which is 1.6 % lower than the solubility in H₂O. The systematic solubility measurements of Salomaa *et al.* (3) in both isotopically pure waters and in their mixtures show that the solubility of CO₂ decreases with increasing deuterium content of water (Fig. 3) supporting the result that CO₂ is more soluble in H₂O than in D₂O at 298.15 K and 101.325 kPa. The measurements of Kratochvil *et al.* (5) at 323.15 and 353.15 K and at higher pressures also indicate a higher solubility of CO₂ in H₂O than in D₂O.

Because of the rather small number of measurements on the solubility of carbon dioxide in D₂O, the results are classified as tentative until confirmed by additional measurements.

AUXILIARY INFORMATION																							
METHOD/APPARATUS/PROCEDURE: The equipment employed for the solubility measurements on CO ₂ was of the Ostwald type. ^{1,2} Before each measurement, the water was freed from dissolved air by boiling under reflux. The CO ₂ which was passed into the absorption apparatus was purified by passing it subsequently through acidic ferric sulfate, iodine, potassium permanganate, and water. The gas was finally dried carefully with magnesium perchlorate.	SOURCE AND PURITY OF MATERIALS: (1) From commercial tank. (2) Norsk Hydro-Elektrisk Kvaestof-aktieselskab, Norway. Analyzed and purified as described in Ref. 3. (3) Distilled, degassed.

AUXILIARY INFORMATION**METHOD/APPARATUS/PROCEDURE:**

The solubility was studied by a static method (1) in an autoclave thermostatted at the required temperature. The autoclave was filled with D₂O, constant specified temperature and pressure were attained, and the autoclave was bubbled with carbon dioxide.

The CO₂ dissolved in D₂O was absorbed by baryta water and the excess of the latter was then titrated with a solution of oxalic acid (2). The CO₂ which remained dissolved in water was titrated with a solution of alkali using phenolphthalein as an indicator (3).

SOURCE AND PURITY OF MATERIALS:

- (1) Carbon dioxide. Alimentary grade (GOST 8050-64) freed beforehand from moisture and oil with the aid of ultrafine glass fibre filters, NaA zeolites, and BAU activated charcoal.
- (2) Water-d₂. 99.78 %

ESTIMATED ERROR:

According to the authors the error of the determination of the composition of the phases is 5 %.

CRITICAL EVALUATION:
AN EVALUATION OF THE SOLUBILITY OF CARBON DIOXIDE IN SEA WATER AT A PARTIAL PRESSURE OF 101.3 kPa

In spite of the importance of carbon dioxide in the ocean, only a few measurements have been made of the solubility of carbon dioxide in sea water at a partial pressure of gas of 101.3 kPa. References 1 - 6 are considered to be of historical interest. They were not used in the present evaluation although they contain some data of value. Since the early measurements, most authors have chosen to extrapolate from data based on the solubility of carbon dioxide in aqueous sodium chloride solutions. This situation persisted until the 1970's when four independent solubility data sets for carbon dioxide in sea water were produced using a variety of techniques.

These four sets of modern measurements were considered for this evaluation. Three of these are of carbon dioxide solubility in natural sea water and one in synthetic or artificial sea water. Two of the independent data sets are extensive enough to allow evaluation and computation of a smoothing equation. Li and Tsui (9) analyzed compositions of equilibrium solutions using infrared spectroscopy, while Murray and Riley (10) used a gravimetric determination. Unfortunately, the agreement between the two sets of measurements is poor: the data of Murray and Riley are as much as 3.8 % lower than those of Li and Tsui at higher temperatures and salinities. The agreement is better at lower temperatures and in distilled water. Weiss (11) examined both data sets and made measurements of his own to determine which were most accurate. Weiss also noted that neither Murray and Riley nor Li and Tsui made corrections for the non-ideal behavior of carbon dioxide. For carbon dioxide, the departure from the ideal gas approximation is much larger than the precision with which its solubility can be measured. Also, neither Murray and Riley nor Li and Tsui made corrections for the dissociation of dissolved hydrated carbon dioxide to form bicarbonate in distilled water. Making these corrections reduces the distilled water values for both of the published data sets by ~ 0.18 % at 273.15 K to ~ 0.46 % at 313.15 K. The 15 measurements that Weiss (11) made confirmed the accuracy of the measurements of Murray and Riley (10). The values of Li and Tsui (9) were shown to be in error by as much as 4 % at the higher temperatures and salinities. The data of Murray and Riley (10), after correction for the effects of non-ideal behavior and for dissociation in the distilled water measurements (11), are believed to be accurate enough to develop a smoothing equation.

Stewart and Munjal (7) made measurements of the solubility of carbon dioxide in synthetic sea water which the evaluator calculated to have a salinity of 34.42 ‰. The compiler estimated the error of these measurements to be ± 1 %, which is greater than the error of the better methods. A comparison of their data with the measurements of Murray and Riley (10) and Weiss (11) revealed their artificial sea water solubility values to be low by an average of 6%. For this reason, the data of Stewart and Munjal (7) were not considered further.

Solubilities of carbon dioxide are generally used in calculations of chemical equilibria and are given typically as amount concentration ($c_1 = n_1/V$) or amount per unit mass of solution or as mass fractions. Weiss (11) evaluated the solubility of carbon dioxide in sea water in terms of the equilibrium constant K_0 , defined as the amount of solute per liter or kilogram of solution, when the fugacity (f) of the solute and the total pressure are both 1 atm. According to the modified form (11) of Henry's law, $m_1 = K_0 f$, where m_1 is the concentration of dissolved gas in molar or gravimetric units and f is the fugacity. In terms of the Bunsen coefficient, $K_0 = \alpha/V^*$ in molar units, or $K_0 = \alpha/V^* \rho$ in gravimetric units, where V^* is the molar volume of the pure real gas at standard temperature and pressure and ρ is the density of the solution. Weiss (11) fitted the corrected Murray and Riley (10) data to the smoothing equation:

$$\ln (K_0 / \text{mol dm}^{-3} \text{ atm}^{-1}) = -58.0931 + 90.5069 (100 \text{ K} / T) + 22.2940 \ln (T/100 \text{ K}) + (S/\text{‰}) [0.027766 - 0.025888 (T/100 \text{ K}) + 0.0050578 (T/100 \text{ K})^2] \quad (1)$$

where S is the salinity (‰) and T is the Kelvin temperature. Weiss (11) also fitted the same data to an equation that represented the solubility in terms of mass of the solution rather than volume,

$$\ln (K_0 / \text{mol kg}^{-1} \text{ atm}^{-1}) = -60.2409 + 93.4517 (100 \text{ K} / T) + 23.3585 \ln (T/100 \text{ K}) \\ + (S/\text{‰})[0.023517 - 0.023656 (T/100 \text{ K}) + 0.0047036 (T/100 \text{ K})^2]. \quad (2)$$

The Murray and Riley (10) data show a standard error of estimate of about 0.3 %, or $1.4 \times 10^{-4} \text{ mol dm}^{-3} \text{ atm}^{-1}$ in terms of K_0 . Weiss (11) gives extensive tables of the carbon dioxide solubility in sea water at various temperatures and salinities from both of the above equations. These equations are recommended for calculation of the solubility of carbon dioxide in sea water.

Although the solubility coefficients of carbon dioxide in sea water are well defined by the above equations, for practical purposes oceanographers and atmospheric scientists require the atmospheric equilibrium solubility for their work. Weiss (8) has proposed equations similar to the above which express the atmospheric equilibrium solubility from moist air at 1 atm total pressure in units of volume (STP), as a function of temperature and salinity. In working with samples from depths in the ocean, it is also advantageous to express atmospheric solubilities in terms of mol kg^{-1} , which are pressure and temperature independent (8). Weiss and Price (12) produced a smoothing equation for carbon dioxide solubility in sea water from the Murray and Riley (10) data in terms of the function F , for a total pressure of 1 atm where $m_1 = x_1 F$ and x_1 is the mole fraction of carbon dioxide in dry air:

$$\ln (F / \text{mol dm}^{-3} \text{ atm}^{-1}) = -160.7333 + 215.4152 (100 \text{ K} / T) + 89.8920 \ln (T/100 \text{ K}) \\ - 1.47759 (T/100 \text{ K})^2 + (S/\text{‰})[0.029941 - 0.027455 (T/100 \text{ K}) \\ + 0.0053407 (T/100 \text{ K})^2] \quad (3)$$

Weiss and Price (12) also fitted the Murray and Riley (10) data to an equation that represented the solubility in terms of mass of the solution rather than volume:

$$\ln (F / \text{mol kg}^{-1} \text{ atm}^{-1}) = -162.8301 + 218.2968 (100 \text{ K} / T) + 90.9241 \ln (T/100 \text{ K}) \\ - 1.47696 (T/100 \text{ K})^2 + (S/\text{‰})[0.025695 - 0.025225 (T/100 \text{ K}) \\ + 0.0049867 (T/100 \text{ K})^2] \quad (4)$$

These two equations can be used to calculate accurately the atmospheric equilibrium solubility of carbon dioxide in sea water between 272.15 K and 313.15 K and salinities between 0 and 40 ‰.

In the following table some numerical values, calculated from equations (1), (2) and (4), are presented for the solubility coefficient K_0 . More extensive tables can be found in references 11 and 12.

T/K	Salinity S/‰				
	0	34	35	36	38

Added by the editor:

Note that Weiss (11) defined the Bunsen coefficient as the volume of gas (STP) absorbed per unit volume of the *solution* at the temperature of the measurement, when the *total* pressure and the fugacity are both 1 atm. According to the usual definition, Bunsen coefficient is the volume of gas (STP) absorbed per unit volume of the solvent at the temperature of measurement and 1 atm partial pressure of gas.

Concerning the thermodynamics of the carbon dioxide system in sea water, there exist several articles in the literature. See for instance the recent paper of Millero (18) and the references therein.

The definitions of salinity and chlorinity have been changed during the years. For these definitions and the salinity - chlorinity relationship, see for instance references 13, 14, 15, and 16.

In 1981 the Joint Panel of Experts on Oceanographic Tables and Standards proposed a new definition of salinity and recommended the use of a new salinity scale - the Practical Salinity Scale 1978 (PSS 78) (13). The Practical Salinity 1978 was defined for the salinities within the salinity range 2 - 42. An extension of the Practical Salinity Scale 1978 to salinities up to 50 is given in reference 17.

AUXILIARY INFORMATION																																																																										
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>In a constant temperature bath, a 2.5l sample of water or sea water solution was saturated with water-saturated carbon dioxide in 3-l round bottom flask fitted with a magnetic stirrer and dip tube. After saturation, 250 mL of the solution was transferred to a volumetric flask also fitted with a dip tube and magnetic stirrer. The carbon dioxide was stripped from the sample by passing carbon dioxide-free air through it. Water and carbon dioxide were removed from the air by passing it through a freeze-out trap cooled to -80°C and then through three absorption tubes, the first of which contained magnesium perchlorate and the other two soda asbestos and magnesium perchlorate. The weight increase of the second absorption tube gave the amount of dissolved carbon dioxide.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Distillers Co., Ltd; 99.9 % by supplier, confirmed by mass spectrometry.</p> <p>(2) Canary Islands vicinity, filtered, acidified to pH 2.2 and boiled.</p> <p>ESTIMATED ERROR:</p> <p>Not given.</p> <p>REFERENCES:</p>

AUXILIARY INFORMATION																																																																									
METHOD/APPARATUS/PROCEDURE: Measurements of CO ₂ solubility were carried out by the microgasometric technique used previously to measure He and Ne solubilities (Ref. 1). The amount of degassed water added to the equilibration chamber was reduced to about one third of the total gas volume. Six to ten minutes were allowed for equilibration. The pH of sea water was brought to 2.2 with addition of sulfuric acid, and the salinity was adjusted by gravimetric determination of the amount of H ₂ O added in the acid solution.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Matheson Gas products. High purity (certified ≥ 99.99 %). (2) Sea water. Surface sea water collected at La Jolla, California. Salinity increased by ≈ 2 ‰, filtered with 0.45 μm filter, poisoned with 1 mg/L HgCl ₂ , salinity determined to 0.004 ‰.																																																																								
ESTIMATED ERROR: The overall accuracy of solubility measurements estimated as ± 0.2 % by author.

<p>COMPONENTS:</p> <p>(1) Carbon dioxide; CO₂; [124-38-9]</p> <p>(2) Electrolyte</p> <p>(3) Water; H₂O; [7732-18-5]</p>	<p>EVALUATOR:</p> <p>H. Lawrence Clever Department of Chemistry Emory University Atlanta, GA 30322, USA August 1995</p>
<p>CRITICAL EVALUATION:</p> <p style="text-align: center;">AN EVALUATION OF THE SOLUBILITY OF CARBON DIOXIDE IN AQUEOUS ELECTROLYTE SOLUTIONS.</p> <p>The solubility of a gas in an aqueous electrolyte solution often approximates the behavior pointed out by Sechenov over 100 years ago (1, 2, 4, 5). It obeys the equation, $(1/c_2)\lg(S^0/S) = k_{\text{sec}}$, where S^0, S represent the solubility of the gas in pure water and in the aqueous electrolyte solution, respectively, \lg is the base 10 logarithm, c_2 is the concentration of the electrolyte, and k_{sec}, the Sechenov salt effect parameter when both the gas and electrolyte concentrations are in volume units.</p> <p>Other gas and electrolyte measures lead to slightly different values of the salt effect parameter. The commonly used forms are:</p> $k_{\text{sec}}/\text{L mol}^{-1} = (1/(c_2/\text{mol L}^{-1})) \lg(c_1^0/\text{mol L}^{-1})/(c_1/\text{mol L}^{-1})$ $k_{\text{secm}}/\text{kg mol}^{-1} = (1/(m_2/\text{mol kg}^{-1})) \lg(m_1^0/\text{mol kg}^{-1})/(m_1/\text{mol kg}^{-1})$ $k_{\text{secx}}/\text{L mol}^{-1} = (1/(c_2/\text{mol L}^{-1})) \lg(x_1^0/x_1)$ $k_{\text{secm}}/\text{kg mol}^{-1} = (1/(m_2/\text{mol kg}^{-1})) \lg(x_1^0/x_1)$ <p>where subscript 1 represents the nonelectrolyte gas, and subscript 2 the electrolyte.</p> <p>The gas solubility ratio in pure water and electrolyte solution, c_1^0/c_1 will be numerically the same using the Bunsen coefficient ratio, α^0/α, or the Ostwald coefficient ratio, L^0/L, as well as the mol L⁻¹ ratio. The molality ratio, m_1^0/m_1, is the same as the Kuenen coefficient ratio, S^0/S, or the solvomolality ratio, A^0/A. The mole fraction ratio, x^0/x, is the same as the inverse Henry's constant ratio, K_H/K_H^0, when the Henry's constant is of the form, $(K_H/\text{kPa}) = (p_1/\text{kPa})/x_1$. The gas mol fractions are usually calculated treating each electrolyte ion as an entity. A more detailed description of these units and the interconversions among them is in the introductory material of Volume 10 of the <i>Solubility Data Series</i> (47).</p> <p>A useful graphical test of salt effect data of either a particular worker or to compare different workers data is to put the Sechenov equation in the form:</p> $\lg S = \lg S^0 - k_s c_2$ <p>and plot $\lg S$ vs. c_2, the linear slope will be the negative of the salt effect parameter in what ever set of units is used for S and c_2. A number of such figures follow in this evaluation.</p> <p>Many workers use electrolyte ionic strength instead of volume concentration, and the salt effect parameter is given in electrolyte ionic strength. There are valid reasons to do this, and we have used the ionic strength designation for most systems except 1-1 electrolytes where ionic strength and electrolyte concentration or molality is numerically the same. The conversion of molar units to ionic strength basis requires dividing by the small whole number of one for 1-1 electrolytes, three for 1-2 and 2-1 electrolytes, four for 2-2 electrolytes, six for 1-3 and 3-1 electrolytes and 15 for 2-3 and 3-2 electrolytes. The solubilities in the mixed electrolyte solutions are plotted as a function of ionic strength. The salt effect parameters in ionic strength are symbolized $k_{\text{st}(c)}$ and $k_{\text{st}(m)}$ for ionic strength in volume concentration and molality units, respectively.</p> <p>For electrolytes other than 1 - 1 and for mixtures of electrolytes we have generally used ionic strength in this evaluation. For electrolytes of higher valent ions the equation becomes $\lg S = \lg S^0 - k_{\text{st}(c,m)} I(c,m)_2$, and for mixed electrolytes $\lg S = \lg S^0 - k_{\text{st}(c,m)} I(c,m)_{\text{total}}$. Often $k_{\text{st}(c,m)} = \{k_{\text{st}(c,m)}_2 + \dots + k_{\text{st}(c,m)}_i\}$, the sum of the individual salt effect parameters 2 to i. $I(c,m)$ means express ionic strength in either volume concentration or molality depending on the data available. The approach was probably first suggested by van Krevelen and Hoffijzer (23).</p> <p>The evaluator would be among the first to point out the simple Sechenov approach is not the best way to treat salt effect data. However, it is fast and convenient to use and gives a simple common basis for the</p>	

comparison of the many data we have here. The user of this evaluation should always consult the original paper, when available, to find what approach the original authors used to explain their data. Some other approaches the user may want to consider are discussed by Markham and Kobe (18, 19), and by the Japanese school of workers (36, 37, 39, 41, 42, 43) who suggest extensions of the Sechenov equation. More recently workers have started to use the Pitzer equation and examples are Rumpf, Maurer and coworkers (56, 59, 60) and He and Morse (57).

Two or more groups of workers have measured the solubility of carbon dioxide in several of the same aqueous electrolyte solutions. Unfortunately often they report values of the solubility of carbon dioxide in water at 298 K which differ by several percent. The difference makes for some difficulty in comparing their results by a plot of $\lg L$ vs. c_2 as we have used here. There are data on over 100 systems containing either one electrolyte, one electrolyte and a non-aqueous nonelectrolyte or two or more electrolytes with water. In general the data for carbon dioxide solubility in aqueous electrolyte solutions show better consistency than the data for less soluble gases reviewed in previous *Solubility Data Series* volumes.

The term salt effect means to many the effect of a strong electrolyte on a property, solubility in this evaluation. However, nonelectrolytes often have a similar magnitude effect on a property. This review contains weak electrolytes, some nonelectrolytes in combination with electrolytes, some inorganic substances in colloidal form and some miscelle forming electrolytes in addition to strong electrolytes.

The systems are given in the order of the standard arrangement for inorganic compounds used by the U. S. National Institute of Science and Technology. The NBS (NIST) Table of Thermodynamic Properties (48) gives a recent description of the standard order and the table is a good example of its use. The number before each system is the standard order number for the electrolyte atom of largest order number.

9 (1) Carbon dioxide + Hydrofluoric acid [7664-39-3] + Water

Cox and Head (28) measured the solubility of carbon dioxide in 0, 2.5 and 5.0 mol L⁻¹ aqueous HF at 293.02, 298.07, 303.02 and 308.00 K. Partial pressures of CO₂ ranged from 94.64 to 107.00 kPa. Results were reported as Henry constants with units mol L⁻¹ atm⁻¹. The salt effect parameter is based on two measurements of the solubility at each of the two HF concentrations. There is a small salting in by the HF. The salt effect parameters are in the table below.

Table 1.

T/K	HF Concentration Range, c_2 /mol L ⁻¹	Salt Effect Parameter $k_{\text{acc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
293.02	2.5, 5.0	-0.013	0.0007	CH (28)
298.07	2.5, 5.0	-0.0096	0.0018	CH (28)
303.02	2.5, 5.0	-0.0081	0.0008	CH (28)

At 308.00 K measurements were made at only one concentration and no calculation of the salt effect parameter was made. The negative sign on the salt effect parameter means salting in. Recall that HF is a weak acid.

10 (1) Carbon dioxide + Hydrochloric acid [7647-01-0] + Water

Geffcken (6) made seven measurements of the solubility of CO₂ in 0 to 2.18 mol L⁻¹ aqueous HCl at 288.15 and 298.15 K and atmospheric pressure. Wolf and Krause (12) made several solubility measurements in 0 - 4 vol % HCl at 293 K. Van Slyke, Sendroy, Hastings and Neill (13) made nine measurements of the solubility of CO₂ in 0.01 to 0.300 mol L⁻¹ HCl at 311.2 K and atmospheric pressure. Robb and Zimmer (34) made eight measurements of the solubility of CO₂ in 0 to 10 mol L⁻¹ HCl at 298.15 K and up to three measurements each at 293.15 and 303.15 K and atmospheric pressure. He and Morse (57) made five measurements of the solubility of CO₂ in 0.01 to 3.0 mol kg⁻¹ HCl at temperatures of 273.2, 298.2, 323.2, 348.2 and 363.2 K and a total pressure near one atmosphere. The actual carbon dioxide partial pressures were 0.927, 0.954, 0.865, 0.611 and 0.305 bar, respectively at the five temperatures.

The measurements of Wolf and Krause (12) were considered doubtful and were not used. Salt effect parameters were calculated from the other data and are given in Table 2 (next page). Figure 1 (next page) shows $\lg \alpha$ vs. m_2 at 298.15 K from the data of Geffcken, Robb and Zimmer, and He and Morse. The data of He and Morse were converted to Bunsen coefficients using their density and partial pressure values and

assuming ideal gas behavior. The data of Geffcken and of Robb and Zimmer show a modest salting-out to about 1.25 mol L^{-1} , then a salting-in as the HCl concentration increases. The data of He and Morse show a regular salting-out up to 3.0 mol kg^{-1} (2.82 mol L^{-1}) HCl of a magnitude almost as large as the salting out by sulfuric acid at the same molalities. The differences between the data of Geffcken and Robb and Zimmer and of He and Morse are serious. The evaluator prefers the data of Geffcken and of Robb and Zimmer because the solubility of carbon dioxide in other aqueous strong acid (HClO_4 and H_2SO_4) solutions show similar trends of salting out and salting in (Figure 1), but only further experimental studies can resolve the differences.

Table 2.

T/K	HCl Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0.499 - 2.18	0.013	0.002	Gf (6)
298.15	0.0 - 1.25	0.011	0.003	Gf (6)
	0.0 - 1.26	0.014	0.001	RZ (34)

 \circ Ref. (25), \square Ref. (34), \blacktriangledown Ref. (57).

He and Morse (57) report their results in mol kg^{-1} of HCl and of CO_2 . Table 3 (next page) gives values of the salt effect parameters, $k_{\text{amm}}/\text{kg mol}^{-1}$, from their data. There is modest salting out over the 0.01 to 3.0 molal HCl range at all temperatures. Until the discrepancy among the results of the three laboratories (6, 34 and 57) is resolved all the data are classed tentative, but use with caution.

Table 3.

T/K	HCl Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{smm}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
273.15	0.01 - 3.00	0.017	0.0015	HM (57)
298.15	0.01 - 3.00	0.016	0.0009	HM (57)
323.15	0.01 - 3.00	0.0090	0.0004	HM (57)
348.15	0.01 - 3.00	0.0060	0.0013	HM (57)
363.15	0.01 - 3.00	0.0059	0.0023	HM (57)

10 (2) Carbon dioxide + Perchloric acid [7601-90-3] + Water

Markham and Kobe (19) measured the solubility of CO_2 at 12 molalities between 0 and 22.84 mol kg^{-1} HClO_4 at 298.15 K. The perchloric acid salts in and the Sechenov salt effect shows a definite curvature which is slightly different for concentration (mol L^{-1}) and for molal (mol kg^{-1}) unit gas solubility values (Figure 1). Limiting slopes were determined up to molalities of 4.00 and 6.00 HClO_4 . Results are in Table 4 below.

Table 4.

T/K	HClO_4 Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{smc}}/\text{L mol}^{-1}$ or $k_{\text{smm}}/\text{kg mol}^{-1}$	Std. Dev. of Slope	Reference
298.15	0 - 6.00	-0.0103 (c)	0.0005	MK (19)
	0 - 6.00	-0.0271 (m)	0.0006	MK (19)
	0 - 4.00	-0.0128 (c)	0.0012	MK (19)
	0 - 4.00	-0.0301 (m)	0.0011	MK (19)

The evaluator has a small preference for the $k_{\text{smm}}/\text{mol kg}^{-1}$ values which appear to give a better fit.

14 (1) Carbon dioxide + Sulfuric acid [7664-93-9] + Water

At least seven papers report the solubility of carbon dioxide in aqueous sulfuric acid. Sechenov (2) reports five solubility values for 8.6 to 100 mass % H_2SO_4 at 290 K, Geffcken (6) reports ten solubility values for 1.0 to 7.6 mol L^{-1} acid at 288.15 and 298.15 K, Christoff (7) reports four solubility values for 0 - 95.6 mass % acid at 293.15 K, Wolf and Krause (12) report five solubility values for 0 to 4 volume percent acid at 293.2 K, Kobe and Williams (16) report solubility values over 0 to 10 mass % acid at 298.15 K, Markham and Kobe (19) report twenty solubility values for 0 to 100 mol % acid at 298.15 K and Shchennikova, Devyatikh, and Korshunov (25) report solubility values for 9.25, 30.5, 36.9, 42, 61.6, 77.6, 78.8 and 84.48 mass % acid over the 288 to 350 K temperature interval.

Results of Wolf and Krause (12) were judged doubtful and were not included in the evaluation. The evaluator judges the Markham and Kobe (19) data at 298.15 K to be the most reliable. Their data shows salting out up to 4 mol kg^{-1} acid, salting in between 4 and 14 mol kg^{-1} acid, salting out between about 15 and 38 mol kg^{-1} acid and then an increasing solubility until the composition reaches pure sulfuric acid. Geffcken's data are usually reliable, however, for this system Geffcken's data do not reproduce the minimum at 4 mol kg^{-1} found by Markham and Kobe. Geffcken's data appear to merge with the Markham and Kobe data as they approach the second minimum (Figure 2). The data of Shchennikova *et al.* (25) scatter badly and do not resolve the discrepancy, agreeing sometimes with Markham and Kobe and other times with Geffcken data. The evaluator prefers the data of Markham and Kobe and has drawn the curves in both figures 1 and 2 with respect to their data.

Figure 1 shows \lg Bunsen coefficient vs. the sulfuric acid molality up to 20 mol kg^{-1} at 298.15 K. The Geffcken data are nearly linear from 0 to 10 mol kg^{-1} acid with a salt effect parameter of $k_{\text{smc}} = 0.0107$. The Markham and Kobe data are linear to only 2 mol kg^{-1} acid with a salt effect parameter of $k_{\text{smc}} = 0.0284$. The Markham and Kobe result is preferred.

Figure 2 (next page) shows the the entire sulfuric acid + water composition range by a plot of \lg Bunsen coefficient vs. 0 to 1.00 mass fraction acid at 298.15 and 290 ± 2 K. There are enough independent data at the lower temperature that parallel the Markham and Kobe data at 298.15 K to give confidence in the reliability of the Markham and Kobe data.

Markham and Kobe fitted their data over the 0 to 10 mol kg⁻¹ sulfuric acid range to the equation:

$$S/S^0 = 0.0885 m_2 + 1/(1 + 0.2159 m_2)$$

where S and S^0 represent the carbon dioxide Kuenen coefficient in acid solution and in pure water, respectively and m_2 the sulfuric acid molality up to 10 mol kg⁻¹ at 298.15 K. The authors state the maximum error of their equation to be about 1 %.

Figure 2. Logarithm of Bunsen coefficient vs. mass fraction of sulfuric acid at 298.15 and 290 ± 2 K.

18 (1) Carbon dioxide + Nitric acid; [7697-37-2] + Water

Geffcken (6) reports ten solubility values between 0 and 2.5 mol L⁻¹ HNO₃ at both 288.15 and 298.15 K. Onda, Sada, Kobayashi, Kito and Ito (36) report the solubility in water and one solution at 298.15 K. Nitric acid salt in. The salt effect parameters are given below.

Table 5.

T/K	HNO ₃ Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0.472 - 2.54	-0.0075	0.0006	Gf (6)
298.15	0.472 - 2.54	-0.0120	0.0005	Gf (6)
	0, 1.482	-0.0119	-	OSKKI (36)
[0 - 2.54	-0.0119	0.0004	combined]

The combined value at 298.15 K is a recommended value. The others are tentative.

19 (1) Carbon dioxide + *ortho*-Phosphoric acid [7664-38-2] + Water

Sada, Kito and Ito (39) report six solubility values in 0 - 2.06 mol L⁻¹ aqueous phosphoric acid at 298.15 K. A linear regression gives a salt effect parameter $k_{\text{acc}} = 0.0577 \text{ L mol}^{-1}$ with a standard deviation about the slope of 0.0032. Van Slyke, Sendroy, Hastings and Neill (13) measured the solubility of carbon dioxide in 0, 0.150 and 0.300 mol L⁻¹ H₃PO₄ at 311.2 K. The salt effect parameter from their data is $(0.0376 \pm 0.0031) \text{ L mol}^{-1}$. The salt effect parameter is given in the molar concentration unit since it is assumed most of the acid is in an undissociated form. The results are classed as tentative.

18 (2) Carbon dioxide + Ammonium chloride [12125-02-9] + Water

The solubility of carbon dioxide in aqueous ammonium chloride has been measured by Mackenzie (3) at four concentration up to almost 6 mol L⁻¹ NH₄Cl at temperatures of 281, 288 and 295 K, by Sechenov (5) at eight concentrations between 0 and 4.8 mol L⁻¹ NH₄Cl at 288.35 K, by Findlay and Shen (9) at six concentration between 0 and 3.19 mol L⁻¹ NH₄Cl at 298.15 K, by Gerecke (35) five concentration between 0 and 5 mol L⁻¹ NH₄Cl at five degree intervals between 288.15 and 333.15 K, by Yasunishi and Yoshida (42) at up to 23 concentration between 0.24 and 5.65 mol L⁻¹ NH₄Cl at temperatures of 288.15, 298.15 and 308.15 K and by Burmakina, Efanov and Shnet (45) at 11 concentrations between 0 and 1.0 mol L⁻¹ NH₄Cl at 298.15 K. A measurement of Passauer (14) of carbon dioxide in saturated aqueous ammonium chloride at 293.15 K was not used in the evaluation.

Table 6.

T/K	NH ₄ Cl Concentration Range, c ₂ /mol L ⁻¹	Salt Effect Parameter $k_{\text{acc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
281	1.23 - 2.51	0.0364	0.0062	Mac (3)
288	1.23 - 4.86	0.0124	0.0020	Mac (3)
288.15	0 - 4.2	0.0317	0.0018	YY (42)
	0 - 5.00	0.0319	0.0081	G (35)
288.35	0 - 1.6	0.0316	0.0014	S (5)
295	1.23 - 4.86	0.0217	0.0022	Mac (3)
298.15	0 - 5.65	0.0242	0.0007	YY (42)
	0 - 5.0	0.0266	0.0086	G (35)
	0 - 3.19	0.0289	0.0020	FS (9)
	0 - 1.00	0.0329	0.0131	BES (45)
308.15	0 - 5.0	0.0080	0.0029	G (35)
318.15	0 - 5.0	-0.0069	0.0048	G (35)
328.15	0 - 5.0	-0.0263	0.0114	G (35)

The data of Yasunishi and Yoshida (42) are probably the most reliable. At 298.15 K they report 24 data points over the 0 to 5.65 mol L⁻¹ range of NH₄Cl. The data show a definite curvature (see Figure 3, next page) and do not extrapolate to a good value of the solubility of carbon dioxide in water. If one uses the nine data between 0.0 and 1.16 mol L⁻¹ one obtains a salt effect parameter of 0.0373 with std. dev. of 0.0012 that extrapolates to the carbon dioxide solubility in water. The Findlay and Shen data show a similar trend. If the data between 0 and 0.944 mol L⁻¹ are used the salt effect parameter is 0.0414 with a standard deviation about the slope of 0.0001 and good extrapolation to the solubility of carbon dioxide in water. The two papers are good evidence of a larger salting-out in dilute solution than in over the full range of salt concentration. The data of Burmakina *et al.* (45) show a pronounced curvature over even the 0 - 1.00 mol L⁻¹ range. Between 0 and 0.005 mol L⁻¹ the salt effect parameter is 1.06 and between 0.25 and 1.00 mol L⁻¹ it is 0.0392. These are interesting results, but until they are confirmed by other workers they are classed doubtful. Yasunishi and Yoshida (42), Findlay and Shen (9) and Sechenov (5) data are classed as tentative with the Yasunishi and Yoshida data preferred.

The data of Mackenzie (3) is doubtful. It shows more scatter and gives smaller salt effect parameters for a given temperature than the results discussed above. The work of Gerecke (35) is difficult to judge. Here, as with other salts, it shows more scatter and salting in at the higher temperatures which is not confirmed for carbon dioxide by other workers. Gerecke's data should be used with caution.

Rumpf, Nicolaisen and Maurer (60) have measured the solubility of carbon dioxide in 4 and 6 mol kg⁻¹ NH₄Cl at six temperatures between 313.14 and 433.10 K and pressures between 0.04 and 9.35 MPa. The

results are similar to the results above at lower temperatures and atmospheric pressure. The solubility data were plotted and values of the solubility taken at 5 MPa at four temperatures. Salt effect parameters calculated from the two molalities at 5 MPa are:

T/K	313	353	393	433
$k_{\text{mm}}/\text{kg mol}^{-1}$	-0.005	0.005	0.005	0.017

The results appear to be consistent with Figures 1 and 2 of the original paper which show a cross over in solubility between 4 and 6 molal salt at 333 K (a change from salting out at low pressure to salting in at high pressure), and a larger salting out at 433 K than at other temperatures. It would be desirable to have the salting in at higher pressures confirmed by additional experimental work. The authors use of the Pitzer equations to correlate their results is of interest.

Figure 3. Logarithm of Ostwald coefficient vs. ammonium chloride concentration.
Dotted line, data of Sechenov (5); solid lines, data of Yasunishi and Yoshida (42).

18 (3) Carbon dioxide + Ammonium bromide [12124-97-9] + Water

Gerecke (35) measured the solubility of carbon dioxide in aqueous ammonium bromide at four concentrations between 0 and 2.0 mol L⁻¹ at five degree intervals between 288.15 and 333.15 K. The results show salting in at 0.5 and 1.0 mol L⁻¹ NH₄Br and salting out at 2.0 mol L⁻¹ at temperatures of 288.15 to 328.15 K. There are no other data to compare with these data so the effect cannot be confirmed. We suggest caution in using the Gerecke data. No salt effect parameters are given from these data.

18 (4) Carbon dioxide + Ammonium sulfate [7783-20-2] + Water

Sechenov (1) measured the solubility of carbon dioxide in aqueous (NH₄)₂SO₄ up to 1.09 mol L⁻¹ at 291.53 K, Gerecke (35) from 0 to 2.0 mol L⁻¹ salt at five degree intervals from 288.15 to 333.15 K, Yasunishi and Yoshida (42) from 0 to 3.87 mol L⁻¹ salt at 288.15, 298.15 and 308.15 K, and Rumpf and Maurer (56) at

near 2.0 and 4.0 mol kg⁻¹ salt at six temperatures between 333.13 and 433.15 K over a total pressure range of about 0.018 to 9.9 MPa. The Rumpf and Maurer data will be treated separately below.

The data of Yasunishi and Yoshida (42) show a small but well defined curvature on the $\lg L$ vs. c_2 plot. Thus, the Sechenov approach is probably valid to only about 1 mol L⁻¹ (ionic strength 3) of ammonium sulfate. Their data were treated over several concentration ranges in Table 7.

Only the data over the 0 - 1 salt concentration range extrapolate back to the value of the carbon dioxide solubility in pure water. We suspect this is common for many salt solutions, we just do not have reliable data to show the effect for most systems.

Table 7.

T/K	(NH ₄) ₂ SO ₄ Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{al}(c)_c}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0 - 0.99	0.0629	0.0009	YY (42)
	0 - 3.35	0.0531	0.0013	YY (42)
	0.99- 3.35	0.0506	0.0015	YY (42)
298.15	0 - 0.85	0.0609	0.0015	YY (42)
	0 - 3.36	0.0518	0.0012	YY (42)
	1.24 - 3.36	0.0459	0.0020	YY (42)
308.15	0 - 1.01	0.0577	0.0009	YY (42)
	0 - 3.87	0.0487	0.0014	YY (42)
	1.32 - 3.87	0.0430	0.0015	YY (42)

The ionic salt effect parameters are compared in Table 8 from the work of Yasunishi and Yoshida, of Sechenov and of Gerecke.

Table 8.

T/K	(NH ₄) ₂ SO ₄ Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{al}(c)_c}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0 - 2.0	0.0541	0.0029	G (35)
	0 - 0.99	0.0629	0.0009	YY (42)
291.53	0 - 1.09	0.0584	0.0013	S (1)
298.15	0 - 2.0	0.0534	0.0033	G (35)
	0 - 0.85	0.0609	0.0015	YY (42)
308.15	0 - 2.0	0.0531	0.0022	G (35)
	0 - 1.01	0.0577	0.0009	YY (42)
318.15	0 - 2.0	0.0513	0.0022	G (35)
328.15	0 - 2.0	0.0530	0.0011	G (35)

The salt effect parameters in ionic strength of Yasunishi and Yoshida and of Sechenov are classed as tentative. The values from Gerecke show more scatter about the regression line and show little temperature dependence. They are also classed as tentative, but should be used with caution.

Rumpf and Maurer (56) made molal solubility measurements of carbon dioxide at about 2.0 and 4.0 mol kg⁻¹ (NH₄)₂SO₄ up to a total pressure near 9.5 MPa at six temperatures between 313.15 and 433.15 K. The evaluator has interpolated solubility values at total pressures of 2.0, 5.0 and 8.0 MPa at four temperatures and calculated a salt effect parameter based on the slope between the two ammonium sulfate molalities. The results are shown in Table 9 (next page).

Table 9.

T/K	$p_{\text{total}}/\text{MPa}$	$k_{\text{amm}}/\text{kg mol}^{-1}$	$k_{\text{al(m)m}}/\text{kg mol}^{-1}$
313.15	2.0	0.0654	0.0218
	5.0	0.0666	0.0222
	8.0	0.0702	0.0234
353.15	2.0	0.0579	0.0193
	5.0	0.0651	0.0217
	8.0	0.0645	0.0215
393.15	2.0	0.0732	0.0244
	5.0	0.0699	0.0233
	8.0	0.0708	0.0236
433.15	2.0	0.0888	0.0296
	5.0	0.0852	0.0284
	8.0	0.0792	0.0264

The increasing pressure has a relatively small influence on the salt effect parameter. The salt effect parameter appears to increase with increasing temperature which is contrary to observations at lower temperatures and atmospheric pressure. The salt effect parameters were obtained in an approximate way by the evaluator from the data of Rumpf and Maurer. The authors give a detailed discussion of their results which should be consulted by anyone making use of their data.

18 (5) Carbon dioxide + Ammonium chloride [12125-02-9] + Ammonium sulfate [7783-20-2] + Water

Yasunishi, Tsuji and Sada (43) measured the solubility of carbon dioxide in aqueous mixed electrolyte of NH_4Cl and $(\text{NH}_4)_2\text{SO}_4$ at 298.15 K. The solutions were:

Mole Fraction NH_4Cl	0.00	0.25	0.50	0.75	1.00
Ionic Strength					
Fraction NH_4Cl	0.00	0.20	0.25	0.50	1.00
Ionic strength Factor	3	2.5	2.0	1.5	1

The ionic strength factor multiplied by the total concentration converts the value to ionic strength.

The evaluator has treated this paper as an entity to itself. Each data set has been fit to a linear equation $\lg L$ vs. c_2 . The negative of the slope is taken as the salt effect parameter which has been put on an ionic strength basis by dividing by the ionic strength factor given above. Salt effect parameters have been calculated using the values for pure NH_4Cl and pure $(\text{NH}_4)_2\text{SO}_4$ and the respective ionic strength fractions. Thus, $k_{\text{al(c)c}}(\text{calc}) = (\text{Ionic strength fraction } \text{NH}_4\text{Cl})(0.0299) + (\text{Ionic strength fraction } (\text{NH}_4)_2\text{SO}_4)(0.0536)$. Results at 298.15 K are in Table 10 below. See also Figure 10B following section 100 (10).

The data for pure ammonium chloride and pure ammonium sulfate are from Yasunishi and Yoshida (42), the present authors have selected 7 of 22 values for ammonium chloride and 7 of 11 values for ammonium sulfate from the earlier paper with no indication as to why this selection was made. Other data from the earlier paper may give different results than observed below.

Table 10.

Total Concentration Range, $(c_2 + c_3)$	Ionic Strength Fraction, NH_4Cl	Salt Effect Parameter, $k_{\text{al(c)c}}$	
		Experimental	Calculated
0.25 - 2.87	0.0	0.0536	-
0.28 - 2.81	0.20	0.0488	0.0489
0.33 - 2.67	0.25	0.0465	0.0476
0.25 - 2.86	0.50	0.0397	0.0418
0.38 - 2.82	1.00	0.0299	-

The salt effect parameter for NH_4Cl seems large (see Table 6), a value of 0.0258 gives calculated values of 0.0480, 0.0467, and 0.0397, which are in much better agreement with the experimental values.

18 (6) Carbon dioxide + Ammonium nitrate [6484-52-2] + Water

Sechenov (5) measured the solubility of carbon dioxide in aqueous NH_4NO_3 at 0 to 10.13 mol L^{-1} at 288.35 K, Gerecke (35) at 0 to 4 mol L^{-1} at five degree intervals from 288.15 to 328.15 K and Onda, Sada, Kobayashi, Kito and Ito (36) at 0 to 3.63 mol L^{-1} at 298.15 K. A measurement of carbon dioxide solubility in aqueous saturated ammonium nitrate at 293.15 K by Passauer (14) was not used in the evaluation. Evaluation results are in Table 11 below.

Table 11.

T/K	NH_4NO_3 Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{s(c)c}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0 - 4.0	0.0474	0.0017	G (35)
288.35	0 - 10.13	0.0213	0.0006	S (5)
298.15	0 - 4.0	0.0488	0.0024	G (35)
	0 - 3.63	0.0187	0.0025	OSKKI (36)
308.15	0 - 4.0	0.0526	0.0051	G (35)
318.15	0 - 4.0	0.0558	0.0090	G (35)
	0 - 2.0	0.0224	0.0040	G (35)
328.15	0 - 4.0	0.0570	0.0093	G (35)
	0 - 2.0	0.0223	0.0026	G (35)

The values above are classed tentative, but we suggest the values from Gerecke be used with caution. They show high scatter about the regression line and an increase with temperature not ordinarily observed. The value of 0.0187 L mol^{-1} at 298.15 K has been used in later sections to calculate a mixed salt effect parameter with CaCl_2 and BaCl_2 with fair success.

20 (1) Carbon dioxide + Arsenic trioxide [1327-53-3] + Water

20 (2) Carbon dioxide + Arsenic pentoxide [1303-28-2] + Water

20 (3) Carbon dioxide + Arsenic trioxide + Arsenic pentoxide + Water

20 (4) Carbon dioxide + Arsenic trioxide + Arsenic pentoxide + Hydrochloric acid [7647-01-0] + Water

Robb and Zimmer (34) report carbon dioxide solubility data in the four systems above plus the carbon dioxide + hydrochloric acid + water system discussed earlier (Section 10 (1)). The authors report measurements at 293.15, 298.15 and 303.15 K in three As_2O_3 solutions up to 0.1113 mol L^{-1} and three As_2O_5 solutions up to 0.1330 mol L^{-1} . They also report measurements in one system containing the two oxides and two systems containing the two oxides and HCl.

There are several inconsistencies in the original paper. No measurements of carbon dioxide solubility in water at 293.15 and 303.15 K are tabulated, but water solubility values at all three temperatures are shown on the figures. Some carbon dioxide solubility values in the mixtures of oxides and HCl are larger than in pure water, but these are ignored in later data treatment. The authors give salt effect parameters with no statement as to the temperature or the effect of temperature.

The following salt effect parameters were determined from the data assuming a water solubility from the small figures in the paper.

Table 12.

T/K	Arsenic Trioxide		Arsenic Pentoxide	
	$k_{smc}/\text{kg mol}^{-1}$	Std Dev Slope	$k_{smc}/\text{kg mol}^{-1}$	Std Dev Slope
293.15	0.207	0.058	0.132	0.014
298.15	0.196	0.014	0.095	0.012
303.15	0.219	0.016	0.148	0.013

The authors reported salt effect parameters of 0.180 for As_2O_3 and 0.129 for As_2O_5 . The averages of the evaluator's values are 0.207 and 0.125, respectively, assuming no temperature effect. The difference between molality and concentration in these solutions is negligible. The data are classed as tentative.

20 (5) Carbon dioxide + Arsenic trisulfide [1303-33-9] + Water

Findlay and Creighton (8) measured the solubility of carbon dioxide in four solutions of 0 - 0.0930 mol L^{-1} As_2S_3 at 298.15 K. The gas pressure ranged from 0.1005 to 0.1707 MPa (754 to 1281 mmHg) without appreciable change in solubility. The salt effect parameter is $k_{\text{acc}} = 0.069 \pm 0.005 \text{ L mol}^{-1}$. The salt effect parameter is about the magnitude one would expect for a molecular solute. The enhanced solubility seen in many colloid systems is not observed. The result is classed tentative.

23 (1) Carbon dioxide + *N, N*-Dimethylmethanamine hydrochloride [593-81-7] + Water

Gerecke (35) has measured the solubility of carbon dioxide in the *N, N*-dimethylmethanamine hydrochloride (trimethylamine hydrochloride) at 6 concentrations between 0 and 4 mol L^{-1} at five degree intervals between 288.15 and 333.15 K. Plots of $\lg L$ vs. c_2 are well defined smooth curves. The first three points (0, 0.25 and 0.50 mol L^{-1} salt) and the entire salt concentration range have been fitted to straight lines. The resulting salt effect parameters are in Table 13 below.

Table 13.

<i>T</i> /K	$\text{C}_3\text{H}_{10}\text{NCl}$ Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{al}(c)}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0 - 0.50	0.068	0.013	G (35)
	0 - 4.0	0.0210	0.0034	
298.15	0 - 0.50	0.085	0.032	G (35)
	0 - 4.0	0.0154	0.0056	
308.15	0 - 0.50	0.118	0.048	G (35)
	0 - 4.0	0.0194	0.0069	
318.15	0 - 0.50	0.145	0.0145	G (35)
	0 - 4.0	0.0199	0.0084	
328.15	0 - 0.50	0.182	0.057	G (35)
	0 - 4.0	0.0198	0.0107	

The increase in the salt effect parameter with temperature in the 0 - 0.50 mol L^{-1} salt concentration range is contrary to most other observations, so too is the salt effect parameter for the entire salt concentration range which goes through a minimum value. The values are classed as tentative. The system is briefly mentioned in the carbon dioxide in aqueous nonelectrolytes volume.

23 (2) Carbon dioxide + *N, N, N*-Trimethylmethanaminium iodide [75-58-1] + Water

Gerecke (35) has measured the solubility of carbon dioxide in the *N, N, N*-trimethyl-methanaminium iodide (tetramethylammonium iodide) at concentrations of 0, 0.1 and 0.19 mol L^{-1} at five degree intervals between 288.15 and 333.15 K. At the lower temperatures the solubility data show salting in at 0.10 mol L^{-1} and salting out at 0.19 mol L^{-1} which does not seem likely. Salt effect parameters are calculated and given below at ten degree intervals between 298.15 and 328.15 K, temperatures at which both salt concentrations show salting out.

Table 14.

<i>T</i> /K	$\text{C}_4\text{H}_{12}\text{NI}$ Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{al}(c)}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
298.15	0 - 0.19	0.085	0.038	G (35)
308.15	0 - 0.19	0.167	0.090	G (35)
318.15	0 - 0.19	0.258	0.073	G (35)
328.15	0 - 0.19	0.370	0.115	G (35)

The results above are out of the ordinary in that they increase rapidly with increasing temperature and that they are of an unusually large magnitude for a 1-1 electrolyte. Past experience with inert gases is that tetra alkyl ammonium salts salt-out little or even salt-in. Carbon dioxide interacts with water and that may in some way account for the different behavior. There are no other data to compare with these. They are classed as tentative, but use with caution until confirmed. The system is also briefly discussed in the carbon dioxide in aqueous nonelectrolytes volume.

23 (3) Carbon dioxide + Ammonium citrate [3012-65-5] + Water

Lloyd (33) measured the solubility of carbon dioxide in water and in 0.053 mol L⁻¹ aqueous ammonium citrate solutions adjusted to pH of 4, 5, 6 and 7 between 299.8 and 333.2 K. The citrate ion ranged from -1 anion, -2 anion and -3 anion at pH's of 4, 5 and 7, respectively. At 299.8 K carbon dioxide was salted out at pH 4 and 5 and salted in a pH 6 and 7. At 333.2 K carbon dioxide was salted in at all pH's. The evaluator suggests the user refer to the data sheet and original paper. No salt effect parameters were calculated by the evaluator. The data are classed as tentative.

24 (1) Carbon dioxide + Silicic acid [1343-98-2] + Water

Findlay and Creighton (8) and Findlay and Williams (10) report carbon dioxide solubility in this system. Findlay and Creighton report measurements in four solutions from 0 to 0.466 mol L⁻¹ H₄SiO₄ at 298.15 K and pressures between 0.0975 and 0.1805 MPa (731 and 1354 mmHg). To the evaluator the change in solubility with pressure appears to be within experimental error. Findlay and Williams report measurements in four solutions from 0 to 0.208 mol L⁻¹ acid at 298.15 K and pressures between 0.0349 to 0.1020 MPa (262 to 765 mmHg). In this set of experiments there is a definite decrease in Ostwald solubility between the lowest and second lowest (ca. 0.052 MPa) gas pressure. The system "salts-in" slightly. The values in the table below are classed tentative.

Table 15.

T/K	H ₄ SiO ₄ Conc. Range, c ₂ /mol L ⁻¹	Salt Effect Parameter k _{sc} /kg mol ⁻¹	Std. Dev. About Slope	Reference
298.15	0.0 - 0.466	-0.0085	0.0035	FC (8)
298.15	0.0 - 0.208	-0.0020	0.0008	FW (10)
298.15	0.0 - 0.466	-0.0087	0.0035	Combined (8)(10)

Suspensions in water of colloidal silica, SiO₂, have negligible effect on the solubility of carbon dioxide (8, 10).

29 (1) Carbon dioxide + Aluminum oxide [1333-84-2] + Water

The solubility of carbon dioxide was measured in three dilute solutions of hydrated aluminum oxide at 293.15, 303.15 and 313.15 K by Shkol'nikova (27). The nature of these solutions is not known. The evaluator has calculated salt effect parameters on the basis of 0.0098, 0.0345 and 0.0414 moles of Al₂O₃ per kilogram of water. Carbon dioxide is salted out with salt effect parameters that have a magnitude about that observed for 1-1 electrolytes.

Table 16.

T/K	Al ₂ O ₃ Molality Range, m ₂ /mol kg ⁻¹	Salt Effect Parameter k _{smc} /kg mol ⁻¹	Std. Dev. About Slope	Reference
293.15	0.0098 - 0.0414	0.153	0.086	Sh (27)
303.15	0.0098 - 0.0414	0.103	0.064	Sh (27)
313.15	0.0098 - 0.0414	0.100	0.063	Sh (27)

Measurements in such dilute solutions are difficult. The results are classed tentative, but they should be used with caution.

29 (2) Carbon dioxide + Aluminum chloride [7446-70-0] + Water

Yasunishi and Yoshida (42) measured the solubility of carbon dioxide at six concentrations between 0 and 2.57 mol L⁻¹ AlCl₃ at 298.15 K. Multiplication by 6 converts the concentrations to ionic strength. The ionic strength basis salt effect parameter is $k_{s(c)c} = 0.0411$ L mol⁻¹ with a standard error about the slope of 0.0004. The result is classed as tentative. Kobe and Williams (16) made measurements in water and in 25 mass % (2.32 mol L⁻¹) at 298.15 K. The two points give an ionic strength salt effect parameter of 0.0380 which is in reasonable agreement with the Yasunishi and Yoshida result.

29 (3) Carbon dioxide + Aluminum sulfate [10043-01-3] + Water

Yasunishi and Yoshida (42) measured the solubility of carbon dioxide at five concentrations between 0 and 0.85 mol L⁻¹ Al₂(SO₄)₃ at 298.15 K. Multiplication by 15 converts the concentrations to ionic strength. The ionic strength basis salt effect parameter is $k_{s(c)c} = 0.0504$ L mol⁻¹ with a standard error about the slope of 0.0008. The result is classed tentative. Kobe and Williams (16) made measurements in water and 20 mass % (0.717 mol L⁻¹) at 298.15 K. The ionic strength salt effect parameter from the two points is 0.0531 which is within reasonable agreement with the Yasunishi and Yoshida result.

33 (1) Carbon dioxide + Zinc chloride [7646-85-7] + Water

Passauer (14) measured the solubility of carbon dioxide in saturated zinc chloride at 293.15 K. No salt effect parameter was calculated because of uncertainty of the solubility of zinc chloride in water. Kobe and Williams (16) measured the solubility of carbon dioxide in 50 mass % (7.34 mol kg⁻¹; 5.74 mol L⁻¹) ZnCl₂ at 298.15 K. The salt effect parameters are $k_{s(m)c} = 0.0149$ and $k_{s(c)c} = 0.0191$. The results are classed tentative.

33 (2) Carbon dioxide + Zinc sulfate [7733-02-0] + Water

Sechenov (5) measured the solubility at five concentrations between 0 and 2.48 mol L⁻¹ ZnSO₄ at 288.35 K. Multiplication by 4 converts the concentrations to ionic strength. The ionic strength salt effect parameter is $k_{s(c)c} = 0.0691$ with a standard deviation about the slope of 0.0009. The result is classed as tentative.

36 (1) Carbon dioxide + Copper (II) sulfate [7758-98-7] + Water

Nahoczky (15) reported a single measurement of the solubility of carbon dioxide in saturated aqueous copper sulfate at 288.15 K. Vázquez, Chenlo and Pereira (61) measured the solubility of carbon dioxide in five solutions between 0 and 1.002 mol L⁻¹ CuSO₄ at 298.15 K and 0.1013 MPa. Vázquez, Chenlo, Pereira and Peaguda (64) measured the solubility of carbon dioxide in four solutions between 0.251 and 1.002 mol L⁻¹ CuSO₄ at five degree intervals between 293.1 and 313.1 K at a pressure of 0.1013 MPa.

No salt effect parameter was calculated from Nahoczky's data because of uncertainty in the saturation concentration of the copper sulfate. Ionic strength salt effect parameters were calculated from the Vázquez *et al.* (61, 64) data. It was assumed the salt concentration values valid at 298.1 K could be used at the other temperatures with negligible error. The concentration salt effect parameters will be four times larger than the values in the table below.

Table 17.

<i>T</i> /K	CuSO ₄ Concentration Range, <i>c</i> ₂ /mol L ⁻¹	Salt Effect Parameter $k_{s(c)c}$ /L mol ⁻¹	Std. Dev. About Slope	Reference
293.1	0.251 - 1.002	0.0595	0.0007	V CPP (64)
298.1	0.0 - 1.002	0.0650	0.0029	V CP (61)
	0.251 - 1.002	0.0601	0.0011	V CPP (64)
303.1	0.251 - 1.002	0.0564	0.0038	V CPP (64)
308.1	0.251 - 1.002	0.0585	0.0028	V CPP (64)
313.1	0.251 - 1.002	0.0522	0.0048	V CPP (64)

The Vázquez *et al.* solubilities show curvature on the lg *L* vs. *c*₂ plot. Much of the curvature comes between 0 and 0.25 mol L⁻¹ salt. The temperature coefficient of the salt effect parameters does not decrease smoothly as expected. The data are classed tentative, but use with caution.

41 (1) Carbon dioxide + Ferric oxide [12259-21-1] + Water

The solubility of carbon dioxide was measured in three dilute solutions of hydrated ferric oxide at 293.15, 303.15 and 313.15 K by Shkol'nikova (27). The nature of these solutions is not known. The evaluator has calculated salt effect parameters on the basis of 0.0063, 0.0315 and 0.0505 moles of Fe_2O_3 per kilogram of water. Carbon dioxide is strongly salted in. Salt effect parameters are below.

Table 18.

T/K	Fe_2O_3 Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{smc}}/\text{kg mol}^{-1}$	Std. Dev. About Slope	Reference
293.15	0.0063 - 0.0505	-0.73	0.02	Sh (27)
303.15	0.0063 - 0.0505	-0.83	0.14	Sh (27)
313.15	0.0063 - 0.0505	-0.63	0.15	Sh (27)

Measurements in such dilute solutions are difficult. The results are classed as tentative, but they should be used with caution.

41 (2) Carbon dioxide + Iron hydroxide oxide [20344-49-4], [1309-33-7] + Water

Gatterer (11) measured the solubility of carbon dioxide in six solutions of 0 to 0.322 mol L^{-1} $\text{Fe}(\text{OH})_3$ at five degree intervals between temperatures of 278.12 and 298.15 K. The author reported eq L^{-1} , the evaluator has used mol L^{-1} . The carbon dioxide solubility is enhanced by the presence of the colloidal solution. However, the $\lg L$ vs. c_2 plot is curved with slope decreasing as the iron compound concentration increases. Both Findlay and Creighton (8) and Findlay and Williams (10) report carbon dioxide solubilities in $\text{Fe}(\text{OH})_3$ solutions at 298.15 K. The first paper reports solubilities at pressures between 0.0995 and 0.1808 MPa (746 and 1356 mmHg) and the second paper at pressures between 0.0311 and 0.0995 MPa (233 and 746 mmHg). At the higher pressure range the Ostwald solubility appears to be independent of pressure, at the lower pressure range there is a noticeable decrease in Ostwald solubility as the pressure increases. The solubility at the common pressure of about 0.0995 MPa differs by 7 to 12 % in the two experiments. These differences may be due to variations in the colloidal nature of these systems.

The evaluator has used only the first three points of Gatterer (0, 0.0237 and 0.0480 mol L^{-1} $\text{Fe}(\text{OH})_3$) to determine the initial salt effect parameter. The values are in Table 19. The Findlay and Creighton data over the higher pressure range showed much less salting in than the data at 0.0995 MPa from the Findlay and Williams paper. The nature of these colloidal solutions depends on method of preparation, aging and other treatment. It appears difficult to obtain solutions of the same stoichiometric concentration with reproducible properties.

Table 19.

T/K	$\text{Fe}(\text{OH})_3$ Conc. Range, $c_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{sc}}/\text{kg mol}^{-1}$	Std. Dev. About Slope	Reference
278.12	0.0 - 0.0480	-0.700	0.011	Ga (11)
283.10	0.0 - 0.0480	-0.813	0.014	Ga (11)
288.11	0.0 - 0.0480	-0.875	0.016	Ga (11)
293.13	0.0 - 0.0480	-0.960	0.003	Ga (11)
298.15	0.0 - 0.0480	-1.071	0.068	Ga (11)
298.15	0.0 - 0.1554	-0.273	0.007	FC (8)
298.15	0.0 - 0.1179	-0.701	0.022	FW (10)

41 (3) Carbon dioxide + Ferrous ammonium sulfate [7783-85-9] + Water

Findlay and Shen (9) measured the solubility of carbon dioxide at four concentrations between 0 and 0.573 mol L^{-1} $(\text{NH}_4)_2\text{SO}_4\cdot\text{FeSO}_4$ (dissolved as the hexahydrate) at 298.15 K. Multiplication by 7 converts the concentration to ionic strength. The electrolyte salts in. The molar salt effect parameter is -0.442 with a standard deviation about the slope of 0.004, the ionic strength salt effect parameter is $k_{\text{st}(c)} = -0.0632 \text{ L mol}^{-1}$ with a standard error about the slope of 0.0005. The values are classed as tentative.

41 (4) Carbon dioxide + Ferriferrocyanide {other names: Iron(III)hexacyanoferrate(II) and Iron(3+)hexacyanoferrate(4-), also Prussian Blue} [14038-43-8], [12240-15-2] + Water

Gatterer (11) has measured the solubility of carbon dioxide in six solutions between 0 and 0.0747 mol L⁻¹ Fe₄[Fe(CN)₆]₃ at five degree intervals between temperatures 278.12 and 298.15 K. The original paper gives the concentrations as equivalents per liter, the equivalent being 1/12 the molecular weight. The solution is described as colloidal. The salt effect parameters are given on a molar basis since the nature of the solution is not known. The solutions show salting in, but the solubility goes through a maximum and then decreases to a value near the value in water at the highest concentration (0.896 eq L⁻¹, 0.0747 mol L⁻¹). The lg *L* vs. *c*₂ plots are linear over only the first three concentrations, and the salt effect parameters are based on the initial slope defined by those three points (0, 0.0105 and 0.0148 mol L⁻¹).

Table 20.

<i>T</i> /K	Fe ₄ [Fe(CN) ₆] ₃ Range, <i>c</i> ₂ /mol kg ⁻¹	Salt Effect Parameter <i>k</i> _{sce} /kg mol ⁻¹	Std. Dev. About Slope	Reference
278.12	0.0 - 0.0148	-0.526	0.013	Ga (11)
283.10	0.0 - 0.0148	-0.644	0.046	Ga (11)
288.11	0.0 - 0.0148	-0.752	0.023	Ga (11)
293.13	0.0 - 0.0148	-0.841	0.013	Ga (11)
298.15	0.0 - 0.0148	-0.937	0.029	Ga (11)

The results are classed as tentative.

ALKALINE EARTH METAL SALTS

A number of measurements have been made on the solubility of carbon dioxide in aqueous solutions of alkaline earth metal salts. An interesting set of values is the Sechenov salt effect parameters for the alkaline earth chlorides at 298.15 K. Values for *k*_{al(c)c} and *R*_p, the cation crystallographic radii (63), are given below:

	<i>k</i> _{al(c)c} /L mol ⁻¹	Cation	10 ¹⁰ <i>R</i> _p /m	Coordination number
MgCl ₂	0.0581 ± 0.0005	Mg ²⁺	0.72	6
CaCl ₂	0.0626 ± 0.0008	Ca ²⁺	1.12	8
SrCl ₂	0.065 ± 0.004	Sr ²⁺	1.26	8
BaCl ₂	0.0715 ± 0.0006	Ba ²⁺	1.42	8

Thus, salting out of carbon dioxide by the alkaline earth chlorides increases as the size of the divalent alkaline earth cation increases. These and other salt effect parameters are evaluated below.

93 (1) Carbon dioxide + Magnesium chloride [7786-30-3] + Water

The system was studied by Yasunishi and Yoshida (42) at 288.15, 298.15 and 308.15 K, by Kobe and Williams (16) in water and 30 mass % (3.92 mol L⁻¹) MgCl₂, and in saturated aqueous MgCl₂ by Nahoczky (15) at 288.15 K and by Passauer (14) at 293.15 K. In addition He and Morse (57) at 273.15, 298.15, 323.15, 348.15 and 363.15 K using molality units. The work from references (42) and (16) is considered the most useful, but the two data sets are treated separately because one is in mol L⁻¹ units and the other in mol kg⁻¹ units. The ionic strength salt effect parameters from the data of Yasunishi and Yoshida (42) are:

<i>T</i> /K	288.15	298.15	308.15
<i>k</i> _{al(c)c} /L mol ⁻¹	0.0637	0.0581	0.0547
Std. dev. slope	0.0019	0.0005	0.0008

The salt effect parameters, which decrease with increasing temperature as expected, are classed as tentative. The two points of Kobe and Williams (16) give a salt effect parameter of 0.0595 at 298.15 K which agrees well with the Yasunishi and Yoshida (42) result. The saturated solution data were not treated because of uncertainty in the saturated MgCl₂ concentration.

The salt effect parameters from the data of He and Morse are in Table 21 next page.

Table 21.

T/K	MgCl ₂ Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{s1(m)m}/\text{kg mol}^{-1}$	Std. Dev. of slope	Reference
273.15	0.1 - 5.0	0.0565	0.0017	HM (57)
298.15	0.1 - 5.0	0.0455	0.0043	HM (57)
323.15	0.2 - 5.0	0.0236	0.0032	HM (57)
348.15	0.1 - 5.0	0.0090	0.0007	HM (57)
363.15	0.1 - 5.0	0.0094	0.0002	HM (57)

The He and Morse data show somewhat more scatter than do the Yasunishi and Yoshida data. The values at 348.15 and 363.15 do not seem to carry the same temperature dependence as the lower temperature values. The data set is classed tentative until more information becomes available.

93 (2) Carbon dioxide + Magnesium sulfate [7487-88-9] + Water

The system was studied by Sechenov (5) at 288.35 K, Markham and Kobe (18) at 273.35, 298.15 and 313.15 K, Gerecke (35) at 5 degree intervals between 288.15 and 333.15 K, Yasunishi and Yoshida (42) at 298.15 K, Nahoczky (15) in aqueous saturated magnesium sulfate and He and Morse (57) at five temperatures between 273.15 and 363.15 K. The ionic strength salt effect parameters from the first four workers are given in Table 22.

The value in [] at 298.15 K is a recommended value from the combined data of Markham and Kobe and of Yasunishi and Yoshida. The values of Gerecke show fair standard deviation of the slope, but they show very little change with temperature, thus they are classed doubtful. The other values are classed tentative. The concentration range can be changed to an ionic strength range by multiplication by four.

Table 22.

T/K	MgSO ₄ Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{s1(c)c}/\text{L mol}^{-1}$	Std. Dev. of slope	Reference
273.35	0.0 - 1.96	0.0788	0.0009	MK (18)
288.15	0.0 - 2.0	0.0717	0.0038	G (35)
288.35	0.0 - 2.617	0.0701	0.0005	S (5)
298.15	0.0 - 1.96	0.0673	0.0007	MK (18)
	0.0 - 2.0	0.0718	0.0020	G (35)
	0.118 - 2.274	0.0669	0.0007	YY (42)
[298.15	0.0 - 2.27	0.0671	0.0004	MK & YY]
313.15	0.0 - 2.7	0.0625	0.0011	MK (18)
	0.0 - 2.0	0.0729	0.0028	G (35)
323.15	0.0 - 2.0	0.0724	0.0032	G (35)
328.15	0.0 - 2.0	0.0724	0.0042	G (35)

The data of He and Morse (57) are reported as molal values for both salt and gas. They report CO₂ solubility values up to 4.0 molal MgSO₄, but the $\lg m_1$ vs. m_2 lines do not extrapolate well to the solubility value in water. Use of only the first three data point extrapolate better, but the standard deviation about the slope is little changed except for the 273 K slope. The salt effect parameters are in Table 23 (next page).

93 (3) Carbon dioxide + Magnesium nitrate [10377-60-3] + Water

Solubility data are reported on the system by Markham and Kobe (18) at 273.35, 298.15 and 313.15 K and by Yasunishi and Yoshida (42) at 298.15 K. The salt effect parameters from the slope of $\lg L$ vs. I_2 plots are given in Table 24 (next page). The individual values are classed as tentative, but the combined data of the two papers at 298.15 K given in [] in Table 24 is classed as recommended. Multiplication of the concentration range by three will give the ionic strength range.

94 (1) Carbon dioxide + Calcium chloride [10043-52-4] + Water

Eight papers report the solubility of carbon dioxide in aqueous calcium chloride solution at atmospheric pressure and four papers report the solubility at pressures of 48 to over 3000 bars. The low and high pressure values will be treated separately.

Mackenzie (3), Sechenov (5), Onda, Sada, Kobayashi, Kito and Ito (36), Yasunishi and Yoshida (42), Wolf and Krause (12), Passauer (14), Kobe and Williams (16) and Eremina, Efanov and Sorokina (53) report the atmospheric pressure experimental measurements. The Wolf and Krause data were not used because the gas was a carbon dioxide/air mixture. The Passauer data was a single point in saturated salt solution and was not used because of uncertainty in the concentration of calcium chloride in saturated solution. Eremina et al. made 11 to 12 solubility measurements over the 0 to 0.025 mol L⁻¹ CaCl₂ range. Their data show linear segments ranging in slopes from -2.2 to -3.4 which the evaluator judges to be doubtful. Measurements in such dilute solutions are difficult and subject to large error [(49) and this volume preliminary material]. The large salt effect parameters from their work are classed doubtful unless confirmed by future work. The Kobe and Williams measurements were in water and in 40 mass % CaCl₂ (5.02 mol L⁻¹). A salt effect parameter was calculated from the two solubilities. It and other values are in Table 25 (next page).

The data at 288.35/289.4 and 298.15 K are shown on a logarithm of Bunsen coefficient vs. calcium chloride ionic strength plot in Figure 4 (next page). The data of He and Morse were included after conversion of their values to Bunsen coefficient and calcium chloride concentration ionic strength using the author's density and partial pressure data, and assuming ideal gas behavior and Henry's law. The 288.35 K line was drawn with respect to the data of Sechenov (5) and the 298.15 K line with respect to the data of Yasunishi and Yoshida (42). The curvature of the 298.15 K line at ionic strength greater than about 6 mol L⁻¹ appears to be confirmed by the points of Onda *et al.* (36) and Kobe and Williams (16), but not the final value of He and Morse (57). The differences in the curves at 288.35 and 298.15 K can be resolved only with further experimental work.

Mackenzie's results are classed doubtful. The salt effect parameters from his solubility values are smaller than those reported by other workers, they show more scatter about the slope and they do not show a regular change with temperature.

Sechenov's value at 288.35 K is classed tentative. Yasunishi and Yoshida's measured the solubility of carbon dioxide up to 4.53 mol L⁻¹ calcium chloride at 298.15 K. Above about 2 mol L⁻¹ calcium chloride there is a definite curvature to the lg *L* vs. *c*₂ data. Thus, we have fitted the salt effect parameter to the near linear part of the data. The data of Onda *et al.* go to 2.17 mol L⁻¹ calcium chloride. Both data sets are classed tentative. The combined result given in [] (Table 25) uses four data points from Yasunishi and Yoshida and eight data points from Onda *et al.* It is the recommended value at 298.15 K.

Yashunishi and Yoshida's data at 308.15 K and the resulting salt effect parameter are classed as tentative.

Table 25.

T/K	CaCl ₂ Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{s(e)}/\text{L mol}^{-1}$	Std. Dev. of slope	Reference
281	0.41 - 1.62	0.0452	0.0048	Mac (3)
288.35	0 - 4.34	0.0700	0.0013	S (5)
289.4	0.41 - 1.62	0.0449	0.0004	Mac (3)
295	0.41 - 1.62	0.0398	0.0044	Mac (3)
298.15	0.18 - 2.17	0.0616	0.0004	OSKKI (36)
	0.23 - 4.53	0.0521	0.0024	YY (42)
	0.23 - 2.0	0.0606	0.0013	YY (42)
	0.0, 5.02	0.0476	-	KW (16)
	0.0 - 0.025	1.01	0.21	EES (53)
[298.15	0.18 - 2.17	0.0626	0.0005	OSKKI & YY]
303	0.41 - 1.62	0.0433	0.0068	Mac (3)
308.15	0.30 - 2.14	0.0548	0.0009	YY (42)
313.15	0.0 - 0.025	0.724	0.154	EES (53)

Figure 4. Logarithm of Bunsen coefficient vs. calcium chloride ionic strength.

The data of He and Morse (57) were measured under somewhat different conditions. They report both the salt and gas in molal units. They used different carbon dioxide pressures at each temperature. The temperatures and pressures of their measurements are (temperature, K)/(pressure/bar): 273.15/0.954, 298.15/0.930, 323.15/0.843, 348.15/0.595 and 363.15/0.297. The measurements are reported for the gas solubility up to 5.0 molal CaCl_2 , but better straight lines that extrapolate to the water solubility value are obtained if the 5.0 molal value is omitted. The salt effect parameters from their data are below.

Table 26.

T/K	CaCl_2 Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{s1(m)m}/\text{kg mol}^{-1}$	Std. Dev. of slope	Reference
273.15	0.10 - 4.00	0.0527	0.0018	HM (57)
298.15	0.1 - 4.0	0.0559	0.0009	HM (57)
323.15	0.1 - 2.71	0.0446	0.0025	HM (57)
348.15	0.1 - 3.0	0.0075	0.0011	HM (57)
363.15	0.1 - 3.0	0.0057	0.0003	HM (57)

There are several inconsistencies in the salt effect parameters. The 273.15 K value is suspected to be low, and the 348.15 and 363.15 K values do not seem to carry on the expected temperature dependence of the lower temperature values. The values are classed as tentative, but use with caution. The evaluator does not believe there is much change with pressure, see the pressure dependent data in Table 27.

Table 27.

393/ 394	0 - 3.91(m)	48 300 600	0.0541 (m) 0.0504 0.0513	0.0038 0.0026 0.0036	PS (22)
423.15	0 - 2.60	48	0.0487	0.0039	MK (40)

The papers of Malinin and Savelyeva (38) and Malinin and Kurovskaya (40) report the solubility of carbon dioxide in aqueous calcium chloride at temperatures of 293.15, 323.15, 353.15, 373.15 and 423.15 K at a pressure of 47.95 bars. The calcium chloride concentration ranges from 0.0 to as high as 6.95 mol L^{-1} . All of the data sets show a definite similar curvature in the $\lg m_1$ vs. c_2 plots. They appear nearly linear up to about 2 mol L^{-1} CaCl_2 and this range is used to obtain a limiting salt effect parameter. The salt effect parameters are given as $k_{s1(c)m}$ values with the CaCl_2 ionic strength in mol L^{-1} and the solubility in mol kg^{-1} . The evaluator calculated approximate molal carbon dioxide solubilities at 293.15 K assuming the solution densities were the same as the aqueous CaCl_2 densities at this temperature. All of the values are classed as tentative.

Prutton and Savage (22) measured the mole fraction solubility of carbon dioxide in water and in 10.1, 20.2 and 30.2 mass percent (0, 1.01, 2.28, and 3.91 molal) CaCl_2 at temperatures of 349, 374, and 393/94 K over a pressure range of 15.2 to 703 bar. The evaluator interpolated mole fraction solubility values at pressures

of 47.3, 300 and 600 bar. The slopes of $\lg x_1$ vs. m_2 were determined by a linear regression at each of the temperatures. The negative of the slopes was converted to an ionic strength scale in molality to give $k_{s1(m)2}/\text{kg mol}^{-1}$ values. The salt effect parameter at 349 K and 47.3 bar appears to be too small and is classed doubtful, the other values are classed tentative.

Plyasunova and Shmulovich (55) measured the solubility of carbon dioxide at 773 K in 10 and 20 mass % CaCl_2 at pressures of 1000, 2000 and 3000 bar. The evaluator calculated molalities of both CO_2 and CaCl_2 from the mass % data and estimated salt effect parameters from the carbon dioxide solubility at the two salt concentrations. The results are:

$p_{\text{total}}/\text{MPa}$	100	200	300
$k_{\text{mm}}/\text{kg mol}^{-1}$	0.291	0.056	0.024
$k_{s1(m)2}/\text{kg mol}^{-1}$	0.097	0.019	0.008

The change of the salt effect parameter with pressure is much larger than at pressures below 10 MPa where little pressure dependence is noted. There are no other data to compare with these and they are classed as tentative.

All of the high pressure salt effect parameters are given in the table above. The results of Malinin and coworkers and of Prutton and Savage cannot be directly compared nor can either set be compared with the atmospheric results without knowledge of the solution density. They appear to be of similar magnitude. There appears to be little effect of pressure on the salting out parameter as one increases the pressure from about 50 to over 600 bars. At 100 to 300 MPa the salt effect parameters decrease (55).

94 (2) Carbon dioxide + Ammonium nitrate [6484-52-2] + Calcium chloride [10043-52-4] + Water

Onda, Sada, Kobayashi, Kito and Ito (36, 37) have measured the solubility of carbon dioxide in aqueous calcium chloride and in aqueous ammonium nitrate + calcium chloride where the salt mol ratio is 1 mole calcium chloride to 3 moles ammonium nitrate (ionic strength ratio 1:1). At 298.15 K and atmospheric pressure the salt effect parameter for the mixed aqueous electrolyte is $k_{s1(e)c} = 0.0372 \text{ L mol}^{-1}$ with a standard deviation about the slope of 0.0010 for the total ionic strength range of 1.66 - 6.33.

If the salts act independently the predicted salt effect parameter would be the average of the calcium chloride and the ammonium nitrate ionic strength salt effect parameters $0.5(0.0187) + 0.5(0.0616) = 0.0402$. The fact that the calculated value is 8 % larger than the experimental value indicates the possibility of some specific interaction between the salts or salts and solvent.

94 (3) Carbon dioxide + Calcium chloride [10043-52-4] + Methanol [67-56-1] + Water

Sada, Kito and Ito (41) measured the solubility of carbon dioxide in methanol-water mixed solutions of calcium chloride at atmospheric pressure at 298.15 K. For comparison with aqueous calcium chloride solutions we used the data of Onda, Sada, Kobayashi, Kito and Ito (36). The ionic strength salt effect parameters are summarized below.

Table 28.

T/K	Calcium chloride Ionic strength Range, $I_2/\text{mol L}^{-1}$	Methanol Mole Fraction	Salt Effect Parameter $k_{s1(e)c}/\text{L mol}^{-1}$	Std. Dev. of slope
298.15	0.54 - 6.51	0.0	0.0616	0.0004
	0.0 - 2.10	0.280	0.0607	0.0007
	0.0 - 2.25	0.389	0.0585	0.0010
	0.0 - 2.19	0.587	0.0635	0.0017
	0.0 - 2.60	0.800	0.0669	0.0003
	0.0 - 2.89	1.000	0.0721	0.0013

The results indicate a minimum in the salting out effect someplace in the methanol mole fraction range between 0.280 and 0.587, probably near mole fraction 0.4 (see also Figure 5 following section 98 (2)). The salt effect parameters are classed as tentative.

94 (4) Carbon dioxide + Calcium nitrate [10124-37-5] + Water

Onda, Sada, Kobayashi, Kito and Ito (36) and Yashunishi and Yoshida (42) have measured the solubility of carbon dioxide in aqueous calcium nitrate solutions at 298.15 K and atmospheric pressure. Their results

compare well and an ionic strength salt effect parameter from their combined data is recommended. The concentration range can be made the ionic strength range of 0.69 - 10.74 by multiplying by three.

Table 29.

<i>T</i> /K	Ca(NO ₃) ₂ Conc. Range, <i>c</i> ₂ /mol L ⁻¹	Salt Effect Parameter <i>k</i> _{al(c)c} /L mol ⁻¹	Std. Dev. of slope	Reference
298.15	0.30 - 2.11	0.0504	0.0004	OSKKI (36)
	0.23 - 3.58	0.0503	0.0006	YY (42)
	0.23 - 3.58	0.0504	0.0005	OSKKI & YY]

95 (1) Carbon dioxide + Strontium chloride [10476-85-4] + Water

Mackenzie (3) measured the solubility of carbon dioxide in aqueous strontium chloride at atmospheric pressure and temperatures of 281, 289.4, 295 and 303 K. His data are the only results we are aware of with this salt. Mackenzie's data often show more scatter than more modern data, however, these data are consistent for the system and are classed as tentative. Note that at 303 K there is considerable improvement in the standard deviation about the slope when the value at 0.868 mol L⁻¹ SrCl₂ is omitted. The ionic strength salt effect parameters are in the table below. The concentration range can be converted to an ionic strength range by multiplication by three.

Table 30.

<i>T</i> /K	SrCl ₂ Conc. Range, <i>c</i> ₂ /mol L ⁻¹	Salt Effect Parameter <i>k</i> _{al(c)c} /L mol ⁻¹	Std. Dev. of slope	Reference
281	0.65 - 2.64	0.0750	0.0043	Mac (3)
289.4	0.65 - 2.64	0.0720	0.0007	Mac (3)
295	0.65 - 2.64	0.0667	0.0033	Mac (3)
303	0.65 - 2.64	0.0643	0.0093	Mac (3)
		0.0590 ^a	0.0043	Mac (3)

^a solubility value at 0.868 mol L⁻¹ SrCl₂ was omitted from fit.

96 (1) Carbon dioxide + Barium chloride [10361-37-2] + Water

The solubility of carbon dioxide in aqueous barium chloride (usually dissolved as the dihydrate) at atmospheric pressure is reported by Mackenzie (3) at 281, 285.7, 288, 289.4, 295 and 303 K, by Sechenov (4) at 288.35 K, by Findlay and Shen (9) at 298.15 K, by Onda, Sada, Kobayashi, Kito and Ito (36) at 298.15 K, by Yasunishi and Yoshida (42) at 298.15 K and by Eremina, Efanov and Sorokina (53) at 298.15 and 313.15 K.

The data of Mackenzie are not consistently reliable and the measurements of Sechenov include only one barium chloride solution, thus both data sets are classed as doubtful. Eremina et al. (53) measured ten solubilities over the 0.0 to 0.050 mol L⁻¹ BaCl₂. Measurements in such dilute solutions are difficult and subject to large error [(49) and this volume preliminary material]. The salt effect parameters from their data in the table below are classed as doubtful until confirmed by future new work. The data from the other three papers are classed as tentative. The result at 298.15 K from the combined data of references (36) and (42) is the preferred tentative salt effect parameter. Results are summarized in Table 31 (next page).

96 (2) Carbon dioxide + Ammonium nitrate [6484-52-2] + Barium chloride [10361-37-2] + Water

Onda, Sada, Kobayashi, Kito and Ito (36, 37) have measured the solubility of carbon dioxide in aqueous barium chloride and in six aqueous mixtures of ammonium nitrate and barium chloride in the ratio of 1 mol BaCl₂ to 2.60 mole NH₄NO₃ (ionic strength ratio 3.00 BaCl₂ to 2.60 NH₄NO₃). The ionic strength salt effect parameter is, *k*_{al(c)c} = 0.0441 with a standard deviation about the slope of 0.0006 for the 0.33 to 1.69 ionic strength range at 298.15 K.

If the two salts act independently one would predict from the salt effect parameters of BaCl₂ and NH₄NO₃ a salt effect parameter of [3(0.0715) + 2.60(0.0187)]/5.60 = 0.0470 which is 6.6 % larger than the experimental value. The result suggests the possibility of a specific interaction in the system.

Table 31.

T/K	BaCl ₂ Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{s(c_2)}/\text{L mol}^{-1}$	Std. Dev. of slope	Reference
281	0.38 - 1.54	-		Mac (3)
285.7	0.766	-		Mac (3)
288	0.1.541	-		Mac (3)
288.35	0 - 1.59	0.068		S (4)
289.4	0.38 - 0.766	-		Mac (3)
295	0.38 - 1.54	0.069	0.006	Mac (3)

	0.155 - 1.564	0.0703	0.0006	YY (42)
	0.371 - 1.082	0.0715	0.0030	OSKKI (36)
	0.0 - 0.050	0.124	0.045	EES (53)
[298.15	0.155 - 1.564	0.0715	0.0006	YY & OSKKI]
303	0.38 - 1.54	0.0740	0.0023	Mac (3)
313	0.0 - 0.050	0.041	0.056	EES (53)

98 (1) Carbon dioxide + Lithium chloride [7447-41-8] + Water

The solubility of carbon dioxide in aqueous lithium chloride solutions is reported in four papers. Sechenov (5) reports the solubility in seven solutions between 0 and 11.83 mol L⁻¹ LiCl at 288.35 K and atmospheric pressure, Gerecke (35) reports the solubility in five solutions between 0 and 3.75 mol L⁻¹ LiCl at five degree intervals between temperatures of 288.15 and 333.15 K. Onda, Sada, Kobayashi, Kito and Ito (36) report the solubility in six solutions between 0 and 5.05 mol L⁻¹ LiCl at 298.15 K. Sada, Kito and Ito (41) report the solubility in four solutions between 0 and 1.18 mol L⁻¹ LiCl at 298.15 K.

The results of Sechenov, of Onda *et al.* and of Sada *et al.* give good straight lines on $\lg L$ vs. c_2 plots and the slopes show fair agreement. Their results are classed tentative. The data of Gerecke presents problems. At the lower temperatures the solubility of carbon dioxide is greater than in water at the concentrations of 0.43, 0.77 and 1.42 mol L⁻¹ LiCl, at the higher temperatures the solubility is greater than in water in the first two solutions. Thus, the initial salt effect is a salting in. There is no hint of any such behavior in the other three papers. If the water value is excluded from the fitted straight line the Gerecke data gives satisfactory slopes for salting out, but the salt effect parameters increases with increasing temperature which has not been confirmed in the work of others. Note that the salt effect parameters from Gerecke's data extrapolate to a solubility in pure water that is 27 % larger than the actual solubility. Gerecke's results are classed doubtful, use with caution. Salt effect parameters are in the table below.

Table 32.

T/K	LiCl Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{scc}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0.43 - 3.75	0.0673	0.0018	G (35)
288.35	0 - 11.38	0.0779	0.0002	S (5)
298.15	0.43 - 3.75	0.0666	0.0015	G (35)
	0 - 5.05	0.0749	0.0014	OSKKI (36)
	0 - 1.18	0.0824	0.0012	SKI (41)
308.15	0.43 - 3.75	0.0736	0.0041	G (35)
318.15	0.43 - 3.75	0.0821	0.0051	G (35)
328.15	0.43 - 3.75	0.1026	0.0031	G (35)

98 (2) Carbon dioxide + Lithium chloride [7447-41-8] + Methanol [67-56-1] + Water

Sada, Kito and Ito (41) measured the solubility of carbon dioxide in methanol-water mixed solvent at four concentrations between 0 and as much as 2.29 mol L⁻¹ LiCl at 298.15 K. The salt effect parameters for the four mixed solvents, pure water and pure methanol are in the table below.

Table 33.

<i>T</i> /K	Lithium Chloride Concentration Range, c_2 /mol L ⁻¹	Methanol Mole Fraction x_3	Salt Effect Parameter $k_{s,e}/L \text{ mol}^{-1}$	Std. Dev. of Slope
298.15	0 - 1.19	0	0.0824	0.0012
	0 - 1.39	0.280	0.0992	0.0032
	0 - 1.13	0.389	0.1066	0.0019
	0 - 2.23	0.587	0.1068	0.0005
	0 - 2.29	0.800	0.1165	0.0019
	0 - 2.26	1.000	0.1243	0.0017

The salting out increases as the mole fraction of methanol increases, but it is not a regular increase, there may be a point of inflection near the 0.389 to 0.587 mole fraction methanol range. Compare the behavior here with the system where calcium chloride (Section 94 (3)) is the electrolyte. See also Figure 5.

Figure 5. CO₂ + (LiCl, CaCl₂) + CH₃OH + H₂O. Salt effect parameter vs. mole fraction of methanol. Symbols: ○ LiCl, Ref. (41); ● CaCl₂, Ref. (41)

98 (3) Carbon dioxide + Lithium bromide [7550-35-8] + Water

Gerecke (35) measured the solubility of carbon dioxide in five solutions of 0 to 1.45 mol L⁻¹ LiBr at five degree intervals at temperatures between 288.15 and 333.15 K. There are no other data on the system. The data show similarities to Gerecke's results in the aqueous LiCl solutions. The solubilities at the first two concentrations (0.2 and 0.4 mol L⁻¹) are larger than in water. The value of the solubility in water fits the lg L vs. c_2 poorly. Omitting the solubility in water value improves the fit, but the scatter is still greater than average. Several values are given in Table 34 (next page) to show trends in the data.

Table 34.

T/K	LiBr Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0.20 - 1.45	0.112	0.002	G (35)
298.15	0.20 - 1.45	0.121	0.011	G (35)
308.15	0.20 - 1.45	0.109	0.009	G (35)
318.15	0.20 - 1.45	0.097	0.009	G (35)

Note that the values above extrapolate to solubility in water values that are too large by 13 to 19 %. The data are classed tentative, but use with caution.

98 (4) Carbon dioxide + Lithium sulfate [10377-48-7] + Water

Lagarote (20) measured the solubility of carbon dioxide in seven solutions between 0 to 2.29 mol L⁻¹ Li₂SO₄ at 290.15 K. Gerecke (35) measured the solubility of carbon dioxide in five solutions from 0 to 2 mol L⁻¹ Li₂SO₄ at five degree intervals between temperatures of 288.15 and 333.15 K. The salt effect parameters in Table 35 have been calculated on an ionic strength basis. For the molar salt effect parameters multiply the values by 3. Agreement between the two workers is poor with the Lagarote salt effect parameter being ca. 10 % larger than the Gerecke value at either 288.15 or 298.15 K.

Table 35.

T/K	Li ₂ SO ₄ Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{a}(c)_e}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0 - 2.0	0.0890	0.0018	G (35)
290.15	0 - 2.29	0.1036	0.0009	L (20)
298.15	0 - 2.0	0.0936	0.0042	G (35)
308.15	0 - 2.0	0.0933	0.0083	G (35)
318.15	0 - 2.0	0.0949	0.0111	G (35)
328.15	0 - 2.0	0.0954	0.0370	G (35)

The Gerecke salt effect parameters show little change with temperature. The lg L vs. c_2 plots reproduce the Gerecke solubility in water poorly being low by 2.5 to 10 % except the 328.15 value which is low by 18.5 %. The standard error of the slope increases at the higher temperatures. The Lagarote line reproduces the water solubility to better than 0.2 %. There is no sure way to decide between the results from the data of Lagarote and of Gerecke until future work resolves the nearly 10 % difference in salt effect parameters. The evaluator has a preference for the data of Lagarote. The Gerecke data are classed as tentative, use with caution.

99 (1) Carbon dioxide + Sodium fluoride [7681-49-4] + Water

Gerecke (35) measured the solubility of carbon dioxide in water and in 0.5 mol L⁻¹ NaF at five degree intervals between temperatures of 288.15 and 333.15 K. Salt effect parameters based on only the two experimental points are given in the table below.

Table 36.

T/K	NaF Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0, 0.5	0.185	-	G (35)
298.15	0, 0.5	0.230	-	G (35)
308.15	0, 0.5	0.327	-	G (35)
318.15	0, 0.5	0.400	-	G (35)
328.15	0, 0.5	0.471	-	G (35)

The results show a strong salting out and a large positive coefficient of temperature. Both properties are unusual for a 1-1 electrolyte. The evaluator knows of no other system showing this behavior. The results are classed as tentative, but use with extreme caution until confirmed by other workers.

99 (2) Carbon dioxide + Sodium chloride [7647-14-5] + Water

The papers on the solubility of carbon dioxide in aqueous sodium chloride are divided into three parts.

i) Measurements at or near atmospheric pressure in which both NaCl and CO₂ are reported in mol L⁻¹ or other volume units, ii) measurements at or near atmospheric pressure in which both NaCl and CO₂ are reported in mol kg⁻¹ or other mass units, and iii) measurements at high pressures regardless of the units used for NaCl and CO₂.

i) Mackenzie (3) measured the solubility of carbon dioxide in four solutions between 1.23 and 4.86 mol L⁻¹ NaCl at temperatures of 281, 288 and 295 K; Sechenov (4, 5) measured the solubility of carbon dioxide in ten solutions between 0 and 5.40 mol L⁻¹ NaCl at 288.35 K; Nahoczky (15) and Passauer (14) measured the solubility of carbon dioxide in water and in saturated NaCl solution at 288/293 K; Kobe and Williams (16) measured the solubility of carbon dioxide in four solutions between 0 and 5.07 mol L⁻¹ at 298.15 K; Rosenthal (24b) measured the solubility of carbon dioxide in four solutions between 0 and 5.06 mol L⁻¹ NaCl at 293.15 K; Yeh and Peterson (31) measured the solubility in two solutions at 0 and 0.155 mol L⁻¹ NaCl at four temperatures between 298.15 and 318.15 K; Gerecke (35) measured the solubility of carbon dioxide in five solutions between 0 and 4.3 mol L⁻¹ at five degree intervals between 288.15 and 333.15 K; Onda, Sada, Kobayashi, Kito and Ito (36) measured the solubility of carbon dioxide in nine solutions between 0 and 3.01 mol L⁻¹ NaCl at 298.15 K; Yasunishi and Yoshida (42) measured the solubility of carbon dioxide in eight or more solutions between about 0.45 and up to 5.10 mol L⁻¹ NaCl at temperatures of 288.15, 298.15 and 308.15 K; and Burmakina, Efanov and Shnet (45) measured the solubility of carbon dioxide at 298.15 K in nine solutions between 0 and 0.200 mol L⁻¹ NaCl. Vázquez, Chenlo and Pereira (61) measured the solubility of carbon dioxide at 298.15 K and 0.1013 MPa in five solutions between 0 and 2.738 mol L⁻¹ NaCl. Vázquez, Chenlo, Pereira and Peaguda (64) measured the solubility of carbon dioxide at 5 degree intervals from 293.1 to 308.1 K and 0.1013 MPa in four solutions from 0.684 to 2.738 mol L⁻¹ NaCl. Wolf and Krause (12) made seven measurements up to saturated NaCl at 293 K. Their data were not used because the gas was a carbon dioxide/air mixture.

Table 37.

<i>T/K</i>	NaCl Concentration Range, <i>c₂</i> /mol L ⁻¹	Salt Effect Parameter <i>k_{sc}</i> /L mol ⁻¹	Std. Dev. of Slope	Reference
279.6	1.23 - 4.86	0.1004	0.0092	Mac (3)
288.15	1.23 - 4.86	0.0971	0.0057	Mac (3)
	0 - 4.3	0.0858	0.063	G (35)
	0.48 - 4.72	0.1010	0.0011	YY (42)
	0, 5.45 (est)	0.0840	-	N (15)
288.35	0 - 5.4	0.1038	0.0012	S (4, 5)

	0 - 0.200	0.116	0.017	BES (45)
	0 - 2.74	0.0998	0.0008	VCP(61)
	0.68 - 2.74	0.1013	0.0013	VCPP (64)
[298.15	0 - 5.10	0.0995	0.0007	(16)(36)(42)(61)]
303.15	0 - 4.3	0.0851	0.0030	G (35)
	0.68 - 2.74	0.0871	0.0043	VCPP (64)
308.15	0 - 4.3	0.0859	0.0035	G (35)
	0.45 - 4.86	0.0931	0.0004	YY (42)
	0.68 - 2.74	0.0926	0.0027	VCPP (64)
313.15	0 - 4.3	0.0836	0.0063	G (35)
318.15	0 - 4.3	0.0798	0.0075	G (35)
323.15	0 - 4.3	0.0782	0.0078	G (35)
328.15	0 - 4.3	0.0833	0.0122	G (35)
333.15	0 - 4.3	0.0814	0.0110	G (35)

The value of $0.0995 \text{ L mol}^{-1}$ at 298.15 K from the combined data of Kobe and Williams (16), Onda *et al.* (36), Yasunishi and Yoshida (42), and Vázquez *et al.* (61) is the only recommended value in Table 37. All of the other data in Table 37 are classed as tentative, but the evaluator prefers the data of Yasunishi and Yoshida as a consistent set of data over a 20 degree temperature interval. The data of Vázquez *et al.* (61, 64) arrived too late to process with the other data. Their data appear to agree well with the earlier data for this system.

The mass percent data of Kobe and Williams (16) were converted to $\text{mol L}^{-1} \text{ NaCl}$ using density data from the *International Critical Tables*. The solubility of NaCl at 288.15 was estimated to be 6.20 mol kg^{-1} or 5.45 mol L^{-1} in the calculation from the data of Nahoczky (15).

In addition to the data in Table 37, salt effect parameters were calculated from the data of Yeh and Peterson (31). They report solubilities for water and for 0.9 mass % NaCl which the evaluator calculated to be $0.155 \text{ mol L}^{-1} \text{ NaCl}$. The salt effect parameters from the two measurements ranged from 0.199 to 0.186 which is about two times the magnitude of the salt effect parameter values in Table 37. We have no confirming evidence this is a real effect in dilute solutions, so we class the result doubtful unless confirmed by future work. Burmakina *et al.* (45) made nine measurements in the 0 - $0.200 \text{ mol L}^{-1} \text{ NaCl}$ range. Measurements in the very dilute solutions are difficult and subject to large error [(49) and this volume introductory material]. They did obtain a somewhat larger salt effect parameter with a relatively large standard error of the slope. This may be an important observation, but until it is confirmed by other workers it also is classified as doubtful.

Figure 6 shows logarithm of Ostwald coefficient vs. sodium chloride concentration (ionic strength) at 288.15 and 298.15 K . The experimental values come from papers published over the last 117 years and show a linear relationship to over 5 mol L^{-1} sodium chloride. The data of He and Morse (57) were converted from molal to volume units assuming ideal gas behavior and Henry's law using density and partial pressure data from their paper. Their results show considerable scatter. This is not surprising in that they made the 298.15 K measurements at a carbon dioxide partial pressure of 0.039 atm and reported the measured solubilities to only two significant figures.

Figure 6. Logarithm of Ostwald coefficient vs. sodium chloride concentration. The Sechenov data (Ref. 5, symbol ▽) are at 288.35 K .

ii) The data of He and Morse (57) are reported in molality for both NaCl and CO_2 . They measured the solubility of carbon dioxide in five to seven solutions between 0.1 or 0.5 to $6.14 \text{ mol kg}^{-1} \text{ NaCl}$ at five temperatures between 273.15 and 363.15 K and carbon dioxide partial pressure between 0.0395 and 0.979 bar (a different pressure at each temperature, see Table 38 next page). The salt effect parameters are in Table 38 (next page).

Table 38.

T/K	p_1/bar	NaCl Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{scm}}/\text{kg mol}^{-1}$	Std. Dev. of Slope	Reference
273.15	0.979	0.5 - 6.0	0.0835	0.0017	HM (57)
298.15	0.0395	0.5 - 6.14	0.0853	0.0029	HM (57)
323.15	0.865	0.5 - 6.14	0.0598	0.0032	HM (57)
348.15	0.611	0.1 - 6.0	0.0204	0.0008	HM (57)
363.15	0.305	0.1 - 6.0	0.0195	0.0010	HM (57)

The salt effect parameters from the data of He and Morse are classed as tentative, but there are several concerns about the results. It is unlikely that the 273.15 K value is smaller than the 298.15 K value. The sharp decrease in salt effect parameter magnitude between 323.15 and 363.15 K needs confirmation. There are nonelectrolyte and salt solutions that show a change from salting out to salting in at about this temperature range, but we have seen no indication of this behavior for carbon dioxide and any salt in this review.

iii) There are several papers that report the solubility of carbon dioxide in aqueous NaCl solution at elevated temperatures and pressures. Ellis and Golding (30) measured the solubility of carbon dioxide in four solutions between 0 and 2.0 mol L⁻¹ NaCl at temperatures between 445 and 607 K and partial pressures between 1.59 and 9.31 MPa CO₂; Takenouchi and Kennedy (32) measured the solubility of carbon dioxide at 0, 1.09 and 4.28 mol kg⁻¹ NaCl at 50 degree intervals between 423.15 and 723.15 K and total pressures between 10.0 and 140.0 MPa; Malinin and Savelyeva (38) measured the solubility of carbon dioxide in up to seven solutions of 0 to 4.46 mol L⁻¹ NaCl at temperatures of 298.15, 323.15 and 358.15 K and a total pressure of 4.795 MPa; Malinin and Kurovskaya (40) measured the solubility of carbon dioxide in up to seven solutions between 0 and 5.92 mol L⁻¹ NaCl at temperatures of 298.15, 373.15 and 423.15 K and a total pressure of 4.80 MPa; Cramer (46) measured the solubility of carbon dioxide in 0, 0.49 and 1.86 mol L⁻¹ NaCl at temperatures between 298.15 and 511.8 K and pressures between 0.8 and 6.2 MPa; and Nighswander, Kalogerakis, and Mehrotra (52) measured the solubility of carbon dioxide in water and in 1 weight percent (0.173 mol kg⁻¹) NaCl at temperatures of about 353.65, 393.15, 433 and 470 K and pressures between about 2.1 and 10.2 MPa. Rumpf, Nicolaisen, Öcal and Maurer (59) measured the solubility of carbon dioxide in 4 and 6 mol kg⁻¹ NaCl between 313 and 433 K and up to 10 MPa total pressure. There is also a 1981 Ph.D. Thesis of Drummond (44) that contains additional data.

All of the papers above contain useful information on the solubility of carbon dioxide as a function of temperature and pressure. However, not all of the experimental studies above are suitable for the evaluation of the effect of electrolyte ionic strength (salt effect parameter) on the carbon dioxide solubility. The paper of Nighswander, Kalogerakis and Mehrotra (52) reports carbon dioxide solubility in water and one mass percent (0.173 mol kg⁻¹) NaCl. The two solubility values over such a small molality range do not lead to reliable salt effect parameters and the paper was not used further. The paper of Takenouchi and Kennedy (32) presented problems. The evaluator converted mass percent data to molality values and made estimates of the salt effect parameter, $k_{\text{scm}}/\text{kg mol}^{-1}$ at 423, 523 and 623 K. The salt effect parameters ranged from 0.023 to 0.26 and showed a high scatter. The data were not treated further. We agree with Dr. R. Crovetto (private communication) who questioned the data treatment in the Drummond (44) thesis for the solubility of carbon dioxide in water because no equation of state could be used with the data as presented.

The evaluator has made calculations from graphically smoothed data from Ellis and Golding (30) and of Cramer (46) under several conditions of temperature and pressure. The salt effect parameters obtained are of larger magnitude and show more scatter about the regression line than other values. From Ellis and Golding at 450 K and 1.59 MPa $k_{\text{scm}}/\text{L mol}^{-1} = 0.105 \pm 0.005$, at 500 K and 4.5 MPa 0.091 ± 0.011 , at 540 K and 6.5 MPa 0.128 ± 0.021 and at 580 K and 6.5 MPa 0.153 ± 0.028 . From Cramer (46) at 300 K and 1.0 MPa $k_{\text{scm}}/\text{L mol}^{-1} = 0.115 \pm 0.037$, at 420 K and 2.0 MPa 0.135 and at 500 K and 6 MPa 0.145.

The most self consistent high temperature and pressure carbon dioxide solubility data appear to be the data of Malinin and Savelyeva (38) and of Malinin and Kurovskaya (40). Most of the plots of $\lg m_1$ vs. c_2 showed a slight concave curvature. A straight line through the data extrapolates to a carbon dioxide solubility in water that is too small by 2.5 to 5.0 % when the full NaCl concentration range of 0 to > 5.0 mol L⁻¹ is used. When the NaCl concentration range is 0 to about 2.0 the line extrapolates satisfactorily to the carbon dioxide solubility in water. Salt effect parameters from several NaCl concentration ranges from the Malinin *et al.* data at 47.95 and 48.0 MPa are in Table 39 (next page).

Table 39.

<i>T/K</i>	NaCl Conc. Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{scm}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
298.15	0 - 2.60	0.0918	0.0011	MS (38)
	0 - 5.04	0.0808	0.0034	MK (40)
	0 - 2.1	0.0922	0.0012	(38 & 40)
	4.04, 5.04	0.0697		MK (40)
323.15	0 - 2.74	0.0791	0.0026	MS (38)
	0 - 1.79	0.0845	0.0019	MS (38)
358.15	0 - 4.46	0.0691	0.0026	MS (38)
	0 - 2.2	0.0780	0.0032	MS (38)
373.15	0 - 5.92	0.0616	0.0032	MK (40)
	0 - 2.0	0.0814	0.0031	MK (40)
	3.98 - 5.92	0.0477		MK (40)
423.15	0 - 5.65	0.0622	0.0042	MK (40)
	0 - 2.52	0.0743	0.0043	MK (40)
	2.52, 5.65	0.054		MK (40)

The evaluator prefers the values from treatment of the 0 - 2 mol L⁻¹ NaCl range. There are inconsistencies in the data at the 373 and 423 K temperatures that require further study.

The data of Rumpf et al. (59) was treated graphically to obtain smoothed solubility values at 2, 5 and 8 MPa total pressure. The solubility values in 4 and 6 mol kg⁻¹ were used to calculate a k_{scm} salt effect parameter. The results based on just the two solubility values are in Table 40.

Table 40.

<i>T/K</i>	$k_{\text{scm}}/\text{kg mol}^{-1}$		
	at 2 MPa	at 5 MPa	at 8 MPa
313	0.052	0.059	-
353	0.055	0.047	0.046
393	0.031	0.046	0.037
433	0.035	0.034	0.037

The Malinin and Kurovskaya values at the high concentrations of NaCl can be compared with the Rumpf et al. values remembering that $k_{\text{scm}} = 1.15 k_{\text{scm}}$. The values are of similar magnitude which gives increased confidence in the reliability of the two sets of data.

99 (3) Carbon dioxide + Hydrochloric acid [7647-01-0] + Sodium chloride [7647-14-5] + Water

Van Slyke, Sendroy, Hastings and Neill (13) measured the solubility of carbon dioxide in solutions of 0.01 mol L⁻¹ HCl and 0, 0.150 and 0.300 mol L⁻¹ NaCl at 311.2 K. The effect of the HCl was considered negligible and the system treated as if only NaCl were present. The NaCl salt effect parameter is $k_{\text{scm}} = (0.0931 \pm 0.0036)$ L mol⁻¹ which agrees well with the value from Yasunishi and Yoshida (42) at 308.15 K. The result is classed tentative. Kobe and Williams (16) made measurements in water and in a mixture which was 2 mass % HCl (0.703 mol kg⁻¹) and 20 mass % NaCl (4.388 mol kg⁻¹) at 298.15 K. The ionic strength salt effect parameter in molality units is 0.0725. It is classed tentative.

99 (4) Carbon dioxide + Nitric acid [7697-37-2] + Sodium chloride [7647-14-5] + Water

Onda, Sada, Kobayashi, Kito and Ito (37) measured the solubility of carbon dioxide in aqueous mixed electrolyte of ionic strength ratio NaCl/HNO₃ 0.3988/0.6012 and 0.6458/0.3542 at 298.15 K. Plots of lg *L* vs. I_{total} were reasonably linear (std error about slope of 0.0014 for both mixtures). The ionic strength salt effect parameters are in Table 41 (next page).

Table 41.

Ionic Strength Ratio NaCl/HNO ₃	Ionic Strength Range $I_{\text{tot}}/\text{mol L}^{-1}$	Salt Effect Parameter ^a , $k_{\text{sl}(c)}/\text{L mol}^{-1}$	Salt Effect Parameter, Calculated	Difference
0.40/0.60	0, 1.40, 2.95	0.0289	0.0399	38 %
0.65/0.35	0 - 2.16	0.0587	0.0644	9.7 %

^a Std dev about slope 0.0014 and 0.0014.

The calculated values use the single salt effect parameters of 0.0004 for HNO₃ and 0.0995 for NaCl. The difference indicates some specific interaction or solution structural change. The effect is definitely not additive. See Figure 11A following section 100 (10).

99 (5) Carbon dioxide + Ammonium chloride [12125-02-9] + Sodium chloride [7647-14-5] + Water

Yasunishi, Tsuji and Sada (43) measured the solubility of carbon dioxide in the mixed electrolyte of 0.0, 0.25, 0.50, 0.75 and 1.00 mole fraction NaCl at 298.15 K. There were eight or nine solutions at each mole fraction. The NH₄Cl values were a selection of the 23 solubility values of Yasunishi and Yoshida (42) and the NaCl values were from the same source (42). The ionic strength salt effect parameters are in Table 42.

The experimental and the calculated salt effect parameters agree well assuming additivity of the salt effects. See also Figure 11A following section 100 (10).

Table 42.

Ionic Strength Ratio NaCl/NH ₄ Cl	Ionic Strength Range $I_{\text{tot}}/\text{mol L}^{-1}$	Salt Effect Parameter ^a , $k_{\text{sl}(c)}/\text{L mol}^{-1}$	Salt Effect Parameter, Calculated	Difference
0.00/1.00	0 - 5.48	0.0252	-	
0.25/0.75	0 - 5.05	0.0424	0.0436	2.8 %
0.50/0.50	0 - 5.18	0.0588	0.0620	5.4 %
0.75/0.25	0 - 5.28	0.0786	0.0803	2.2 %
1.00/0.00	0 - 5.10	0.0987	-	

^a Std. dev. about slopes are 0.0015, 0.0011, 0.0011, 0.0011 and 0.0009, respectively.

99 (6) Carbon dioxide + Ammonium nitrate [6484-52-2] + Sodium chloride [7647-14-5] + Water

Onda, Sada, Kobayashi, Kito and Ito (37) measured the solubility of carbon dioxide in mixed electrolyte of 0.335, 0.500 and 0.635 mole fraction NaCl at 298.15 K. There were five to seven solutions at each mole fraction. To test the additivity of the salt effects salt effect parameters of 0.0995 and 0.0187 were used for NaCl and NH₄NO₃, respectively.

Table 43.

Ionic Strength Ratio NaCl/NH ₄ NO ₃	Ionic Strength Range $I_{\text{tot}}/\text{mol L}^{-1}$	Salt Effect Parameter ^a , $k_{\text{sl}(c)}/\text{L mol}^{-1}$	Salt Effect Parameter, Calculated	Difference
0.335/0.665	0 - 2.97	0.0412	0.0458	11 %
0.50/0.50	0 - 2.78	0.0551	0.0591	7.3 %
0.635/0.365	0 - 3.05	0.0657	0.0701	6.7 %

^a Std. dev. about slope of 0.0006, 0.0009 and 0.0016, respectively.

The salt effects are not additive. All results are classed as tentative. See also Figure 11B following section 100 (10).

99 (7) Carbon dioxide + Magnesium sulfate [7487-88-9] + Sodium chloride [7647-14-5] + Water

Yasunishi, Tsuji and Sada (43) measured the solubility of carbon dioxide in mixed electrolyte of 0.0, 0.25, 0.50, 0.75 and 1.00 mole fraction NaCl [0.0, 0.077, 0.260, 0.428 and 1.00 ionic strength fraction NaCl] at 298.15 K. Six solutions were measured at each mole fraction. The results are in the Table 44 (next page).

Table 44.

Ionic Strength Ratio NaCl/MgSO ₄	Ionic Strength Range $I_{\text{tot}}/\text{mol L}^{-1}$	Salt Effect Parameter ^a , $k_{\text{sl(c)c}}/\text{L mol}^{-1}$	Salt Effect Parameter, Calculated	Difference
0.00/1.00	0 - 9.10	0.0665	-	
0.077/0.923	0 - 6.68	0.0683	0.0691	1.2 %
0.260/0.740	0 - 5.46	0.0726	0.0755	4.0 %
0.428/0.572	0 - 3.81	0.0804	0.0863	1.1 %
1.00/0.00	0 - 2.49	0.1010	-	

^a Std. dev. of slopes are 0.0007, 0.0007, 0.0005, 0.0011, 0.0018, respectively.

The electrolytes act with near additivity. The results are classed tentative. See also Figure 11B following section 100 (10).

99 (8) Carbon dioxide + Calcium chloride [10043-52-4] + Sodium chloride [7647-14-5] + Water

Malinin and Savelyeva (38) measured the solubility of carbon dioxide in water and in one mixture of CaCl₂ and NaCl at a total ionic strength of 2.65 at 298.15 K and 47.95 bar. The solubility in water and in the one solution gives salt effect parameters $k_{\text{sl(c)m}} = 0.032$ and $k_{\text{sl(c)c}} = 0.040$. The results are classed tentative.

99 (9) Carbon dioxide + Calcium sulfate [7778-18-9] + Sodium chloride [7647-14-5] + Water

He and Morse (57) measured the solubility of carbon dioxide in six solutions of 0.1 to 6.0 mol kg⁻¹ NaCl and 0.01 mol kg⁻¹ CaSO₄ at temperatures of 273.15, 298.15, 323.15, 348.15 and 363.15 K. In other mixed electrolyte studies the electrolytes have been at some constant ionic strength ratio. In this study the calcium sulfate is near its saturation value at 0.01 mol kg⁻¹ (ionic strength 0.04) in all solutions.

The data were treated to obtain $k_{\text{sl(m)m}}/\text{kg mol}^{-1}$ values in the table below.

Table 45.

T/K	p_1/bar	Ionic Strength Range, $I_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{sl(m)m}}/\text{kg mol}^{-1}$	Std. Dev. of Slope	Reference
273.15	0.979	0.14 - 6.04	0.0866	0.0083	HM (57)
298.15	0.954	0.14 - 6.04	0.0852	0.0024	HM (57)
323.15	0.865	0.14 - 6.04	0.0623	0.0007	HM (57)
348.15	0.611	0.14 - 6.04	0.0286	0.0020	HM (57)
363.15	0.305	0.14 - 6.04	0.0227	0.0011	HM (57)

The results parallel within 0.1 to 4.2 % the results for sodium chloride alone at the first three temperatures. At 348 and 363 K the calcium sulfate containing solutions show higher salt effect parameters by 40 and 16 %, respectively. The results are not reliable enough to draw conclusions about the effect of the calcium sulfate in the mixed electrolyte.

99 (10) Carbon dioxide + Ammonium nitrate [6484-52-2] + Barium chloride [10361-37-2] + Sodium chloride [7647-14-5] + Water

Onda, Sada, Kobayashi, Kito and Ito (37) measured the solubility of carbon dioxide in five solutions of a mixed electrolyte of NH₄NO₃/BaCl₂/NaCl of mole ratio 3/1/3 which is ionic strength ratio 1/1/1. A plot of $\lg L$ vs. I_2 over the 0 - 0.633 ionic strength range gives the salt effect parameter of $k_{\text{sl(c)c}} = 0.0612$ with a standard error about the regression line of 0.0010. A calculated salt effect parameter obtained by summing one third values of each pure electrolyte salt effect parameter gives 0.0632 which is 3.3 % larger than the experimental value. The result is classed as tentative.

99 (11) Carbon dioxide + Sodium chloride [7647-14-5] + Glucose [50-99-7] + Water

Yuan and Yang (58) measured the solubility of carbon dioxide in six solutions of 0 to 3.00 mol kg⁻¹ sodium chloride in a 15 mass % glucose-water mixture at ten degree intervals between 278.15 and 318.15 K. The salt effect parameters on a molality basis are in Table 46 (next page).

Table 46.

T/K	NaCl Concentration Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{amm}}/\text{kg mol}^{-1}$	Std. Dev. about Slope	Reference
278.15	0 - 3.00	0.086	0.007	YuYa (58)
288.15	0 - 3.00	0.064	0.011	YuYa (58)
298.15	0 - 3.00	0.063	0.009	YuYa (58)
308.15	0 - 3.00	0.048	0.008	YuYa (58)
318.15	0 - 3.00	0.042	0.004	YuYa (58)

The data show more than an average amount of scatter on the $\lg m_1$ vs. m_2 plot. Our values of the salt effect parameter differ from the author's values especially at temperatures of 288 and 308 K. The results show smaller magnitude salt effect parameters in the glucose solution than in pure water. The data are classed as tentative.

99 (12) Carbon dioxide + Sodium chlorate [7775-09-9] + Water

Sechenov (5) measured the solubility of carbon dioxide at four concentrations between 0 and 6.57 mol L⁻¹ NaClO₃ at 288.35 K. The salt effect parameter is $k_{\text{acc}} = 0.0874 \text{ L mol}^{-1}$ with a standard error of the slope of 0.0020. The value is classed tentative.

99 (13) Carbon dioxide + Sodium perchlorate [7601-89-0] + Water

Gerecke (35) measured the solubility of carbon dioxide at five concentrations between 0 and 1.6 mol L⁻¹ NaClO₄ at five degree intervals between the temperatures of 288.15 and 333.15 K. The salt effect parameters are below.

Table 47.

T/K	NaClO ₄ Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{acc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0 - 1.6	0.103	0.006	G (35)
298.15	0 - 1.6	0.110	0.012	G (35)
308.15	0 - 1.6	0.125	0.015	G (35)
318.15	0 - 1.6	0.156	0.022	G (35)
328.15	0 - 1.6	0.190	0.022	G (35)

It is important to point out that the trend more commonly seen for inorganic gases that do not have a special interaction with water in aqueous electrolytes is a small salt effect parameter that decreases with increasing temperature. The relatively large salt effect parameter that increases with temperature is unusual. The results are classed as tentative, but use with caution until confirmed by other workers.

99 (14) Carbon dioxide + Sodium bromide [7647-15-6] + Water

Sechenov (5) measured the solubility of carbon dioxide at four concentrations between 0 and 6.71 mol L⁻¹ NaBr at 288.35 K. Rosenthal (24b) measured the solubility at five concentrations between 0 and 7.08 mol L⁻¹ at 293.15 K. Gerecke (35) measured the solubility at five concentrations between 0 and 4.50 mol L⁻¹ at five degree intervals between temperatures of 288.15 and 333.15 K. Salt effect parameters from these papers are compared in Table 48 (next page). Vázquez, Chenlo, Pereira and Peaguda (64) measured the solubility at seven concentrations between 0.389 and 2.721 mol L⁻¹ NaBr at 298.1 K and 0.1013 MPa. In an earlier paper (61) they reported the solubility of carbon dioxide in water at the same conditions of temperature and pressure. Their (61, 64) values of the salt effect parameter fitted with and without the solubility in water are in Table 48.

This is one of only a few systems for which the salt effect parameters from the data of Gerecke show the expected magnitude and temperature coefficient. However, the data do show more scatter than the data of Sechenov and of Rosenthal. The data of Vázquez *et al.* (61, 64) show a definite curvature on a $\lg L$ vs. c_2 plot with much of the curvature between 0 and 0.4 mol L⁻¹ NaBr. At 298.15 K the solubility values of Vázquez *et al.* are significantly lower than the values of Gerecke for a given NaBr concentration. [See also Figure 10 following section 100 (7)]. All of the results are classed tentative with a slight preference for the values of Sechenov and of Rosenthal at 288.5 and 293.15 K, respectively. At 298.15 K we cannot make a choice between the data of Gerecke and of Vázquez *et al.*, both data sets should be used with caution.

Table 48.

<i>T/K</i>	NaBr Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0 - 4.50	0.0875	0.0059	G (35)
288.35	0 - 6.71	0.0981	0.0005	S (5)
293.15	0 - 7.08	0.0874	0.0006	R (24b)
	0 - 4.50	0.0831	0.0044	G (35)
298.15	0 - 4.50	0.0779	0.0041	G (35)
	0 - 2.72	0.0905	0.0043	VCP (64)
	0.39 - 2.72	0.0842	0.0029	VCP (64)
308.15	0 - 4.50	0.0709	0.0025	G (35)
318.15	0 - 4.50	0.0680	0.0010	G (35)
328.15	0 - 4.50	0.0520	0.0037	G (35)

99 (15) Carbon dioxide + Sodium iodide [7681-82-5] + Water

Rosenthal (24b) measured the solubility of carbon dioxide at four concentrations between 0 and 6.01 mol L⁻¹ NaI at 293.15 K. Gerecke (35) measured the solubility at five concentrations between 0 and 4.0 mol L⁻¹ at five degree intervals between temperatures of 288.15 and 333.15 K. Salt effect parameters from their data are in the table below.

Table 49.

<i>T/K</i>	NaI Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sc}}/\text{L mol}^{-1}$	Std. Dev. of Slope	Reference
288.15	0 - 4.00	0.0792	0.0033	G (35)
293.15	0 - 6.01	0.0726	0.0023	R (24b)
	0 - 4.00	0.0779	0.0025	G (35)
298.15	0 - 4.00	0.0774	0.0017	G (35)
308.15	0 - 4.00	0.0750	0.0046	G (35)
318.15	0 - 4.00	0.0577	0.0101	G (35)
328.15	0 - 4.00	0.0400	0.0161	G (35)

The results are classed as tentative. There seems little reason to pick one result over the other at 293.15 K. The difference could be due to the smaller NaI concentration range used by Gerecke since with some systems the slope decreases at the higher concentrations (ionic strengths). Gerecke's results at 318.15 and 328.15 K scatter badly and these two results should be used with caution.

99 (16) Carbon dioxide + Sodium hydrogen sulfite [7631-90-5] + Water

Onda, Sada, Kobayashi, Kito and Ito (36) measured the solubility of carbon dioxide at four concentrations between 0 and 2.02 mol L⁻¹ NaHSO₃ at 298.15 K. The salt is not 100 per cent dissociated so the molar concentration salt effect parameter is reported. It is $k_{\text{sc}} = 0.1434 \text{ L mol}^{-1}$ with a standard deviation of the slope of 0.0031. The result is classed as tentative. If the salt was 100 % dissociated the ionic strength salt effect parameter, $k_{\text{al(c)s}}$, would be the value above divided by 3.

99 (17) Carbon dioxide + Sodium sulfate [7757-82-6] + Water

The evaluation of the solubility of carbon dioxide in aqueous solutions of sodium sulfate is divided into three parts. *i*) Papers reporting measurements at or near atmospheric pressure in which both Na₂SO₄ and CO₂ are reported in mol L⁻¹ or other volume units; *ii*) papers reporting measurements at or near atmospheric pressure in which both Na₂SO₄ and CO₂ are reported in mol kg⁻¹ or other mass units; and *iii*) papers which report measurements at high pressures and temperatures regardless of the units used for Na₂SO₄ and CO₂.

i) Sechenov (5) reported the solubility of carbon dioxide in eight solutions from 0 to 2.00 mol L⁻¹ sodium sulfate at 288.35 K, Markham and Kobe (18) reported the solubility of carbon dioxide in five solutions from 0 to 1.435 mol L⁻¹ sodium sulfate at 298.15 and 313.15 K, Shchennikova, Devyatikh and Korshunov (26)

reported the solubility of carbon dioxide in six solutions of 0.20 to 1.68 mol L⁻¹ sodium sulfate at one to five temperatures between 298.15 and 348.15 K, Gerecke (35) measured the solubility of carbon dioxide in four solutions between 0 and 1.0 mol L⁻¹ sodium sulfate at five degree intervals between 288.15 and 333.15 K, Onda, Sada, Kobayashi, Kito and Ito (36) reported the solubility of carbon dioxide in four solutions from 0 to 1.44 mol L⁻¹ sodium sulfate at 298.15 K and Yasunishi and Yoshida (42) reported the solubility of carbon dioxide in up to fifteen solutions from 0 to 2.21 mol L⁻¹ sodium sulfate at 288.15, 298.15 and 308.15 K. The concentrations have been changed to ionic strength by multiplying by 3. The ionic strength salt effect parameters from the papers are given in the table below.

Table 50.

<i>T/K</i>	Na ₂ SO ₄ Conc. Range, <i>c</i> ₂ /mol L ⁻¹	Salt Effect Parameter <i>k</i> _{sl(c)₂} /L mol ⁻¹	Std. Dev. of Slope	Reference
288.15	0 - 1.00	0.0829	0.0102	G (35)
	0 - 1.06	0.1072	0.0049	YY (42)
288.35	0 - 2.00	0.1063	0.0004	S (5)
298.15	0.2 - 1.68	0.1001	0.0062	SDK (26)
	0 - 1.00	0.0836	0.0132	G (35)
	0 - 1.435	0.0991	0.0006	MK (18)
	0 - 1.44	0.0982	0.0009	OSKKI (36)
	0 - 2.21	0.0981	0.0004	YY (42)
	[0 - 2.2	0.0983	0.0005	(18)(36)(42) combined]
308.15	0 - 1.00	0.0826	0.0188	G (35)
	0 - 1.76	0.0894	0.0009	YY (42)
313.15	0 - 1.435	0.0913	0.0004	MK (18)
318.15	0 - 1.00	0.0869	0.0195	G (35)
323.15	0.42 - 1.68	0.1108	0.0057	SDK (26)
328.15	0 - 1.00	0.0904	0.0199	G (35)

Shchennikova, Devyatykh and Korshunov (26) reported salt effect parameters from their smoothed data on a natural logarithm mol fraction basis. The evaluator converted their values to our *k*_{sl(c)₂}/L mol⁻¹ values. The results are:

<i>T/K</i>	298	303	313	323	338
<i>k</i> _{sl(c)₂}	0.094	0.097	0.104	0.124	0.221

The values at 298 and 303 K seem reasonable, but the steady increase in salt effect parameter with temperature is contrary to our experience and the values at the higher temperatures are classed doubtful.

Gerecke's (35) data give smaller slopes than other data, show more scatter about the regression line and extrapolate to a carbon dioxide in water value that is 5 to 8.5 % low. The data are classed doubtful.

The combined data of Markham and Kobe (18), Onda et al. (36) and of Yasunishi and Yoshida (42) give a recommended salt effect parameter at 298.15 K of 0.0983 ± 0.0005 L mol⁻¹.

Figure 7 (next page) shows logarithm of Bunsen coefficient vs. the sodium sulfate ionic strength at 288.15 and 298.15 K and one atm. The data are best fitted by a straight line. The data of He and Morse were converted from their molality values to Bunsen coefficients and concentration ionic strength using their density and partial pressure values and assuming ideal gas behavior and Henry's law. Their results at 298.15 K deviate considerably from the other 298.15 K values.

ii) He and Morse (57) report the molality solubility of carbon dioxide in 4 or 5 solutions ranging from 0.01 up to 3.00 mol kg⁻¹ sodium sulfate at temperatures of 273.15, 298.15, 323.15, 348.15 and 363.15 K and carbon dioxide partial pressures of 0.305 to 0.979 bar. In addition Markham and Kobe (18) and Gerecke (35) report their data so values of the salt effect parameter, *k*_{sl(m)₂}, can be obtained. Salt effect parameters from these data are given in Table 51 (next page).

Agreement in Table 51 is not good. The evaluator prefers the values from the data of Markham and Kobe since their results agree well with other reliable workers when mol L⁻¹ units are used.

Figure 7. Logarithm of Bunsen coefficient vs. sodium sulfate ionic strength.

Table 51.

T/K	p_1/bar	Na_2SO_4 Molal Range $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{s1(m)m}/\text{kg mol}^{-1}$	Std. Dev. of slope	Reference
273.15	0.979	0.01 - 0.3	0.0663	0.0129	HM (57)
	0.979	0.01 - 0.1	0.106	0.065	HM (57)
298.15	0.954	0.1 - 2.0	0.0619	0.0047	HM (57)
		0.1 - 1.0	0.0654	0.0033	HM (57)
	0 - 1.5	0.0911	0.0016	MK (18)	
	0 - 1.05	0.0754	0.0132	G (35)	
313.15		0 - 1.5	0.0835	0.0011	MK (18)
		0 - 1.05	0.0776	0.0199	G (35)
323.15	0.865	0.1 - 3.0	0.0287	0.0044	HM (57)
	0.865	0.1 - 1.0	0.0466	-	HM (57)
348.15	0.611	0.1 - 3.0	0.0134	0.0028	HM (57)
	0.611	0.1 - 1.0	0.0295	0.0027	HM (57)
363.15	0.305	0.1 - 3.0	0.0223	0.0006	HM (57)

iii) Corti, Krenzer, de Pablo and Prausnitz (54) measured the solubility of carbon dioxide in solutions of 0.95 to 2.72 mol kg⁻¹ sodium sulfate at temperatures of 323.15 and 348.15 K and total pressures between 37.9 and 145.1 bar. Rumpf and Maurer (56) measured the solubility of carbon dioxide in two solutions of about 1 and 2 mol kg⁻¹ sodium sulfate at seven temperatures between 313 and 433 K over a total pressure interval of 0.019 to 9.71 MPa.

The evaluator has interpolated data from both papers at several temperatures and pressures. There are really solubility measurements at only two molalities of sodium sulfate. Therefore any salt effect parameters derived from these data are of limited value. The values obtained this way are in the table below.

Table 52.

T/K	$p_{\text{total}}/\text{MPa}$	$k_{\text{sum}}/\text{kg mol}^{-1}$	$k_{\text{sl(m)m}}/\text{kg mol}^{-1}$	Reference

	8.0	0.163	0.054	

The data in these two papers deserve better treatment than we have time to give them in this brief review. The salt effect parameters above should be used between 1.0 and 2.0 molal (3.0 and 6.0 ionic strength) sodium sulfate. The results indicate only a small effect of pressure on salting out and a slight decrease in the salting out as temperature increases.

99 (18) Carbon dioxide + Sulfuric acid [7664-93-9] + Sodium sulfate [7757-82-6] + Water

Kobe and Kenton (17) measured the solubility of carbon dioxide in one solution which was 0.90 molal H_2SO_4 and 1.76 molal Na_2SO_4 at 298.15 K. The total ionic strength is 7.98 mol kg^{-1} . The evaluator used the solubility of carbon dioxide in water from Markham and Kobe (18) to calculate an ionic strength salt effect parameter of 0.0609. The value is less than the contribution of sodium sulfate alone in a solution to which it contributes 0.662 fraction ionic strength. The sulfuric acid is contributing an apparent salting in effect. The result is classed tentative. Kobe and Williams (16) measured the solubility in water and in a solution that was 5 volume % H_2SO_4 and 20 mass % Na_2SO_4 . The solubility values are classed tentative, but no effort was made to calculate a solubility parameter.

Shchennikova, Devyatykh and Korshuhov (26) measured the solubility of carbon dioxide in solutions which ranged between 0.2 to 1.3 mol L^{-1} sodium sulfate and 0.24 to 5.66 mol L^{-1} (2.3 to 42 mass %) sulfuric acid at temperatures between 298.15 and 348.15 K. In all 11 solutions were studied. Assuming 100 % dissociation of both salt and acid the total ionic strength ranged from 1.31 to 18.84 mol L^{-1} . All eleven solutions were studied at 298.15 K and only up to three solutions studied at the other temperatures. At 298.15 K the five data points between ionic strength 3.6 and 6.9 fitted well a Sechenov plot with a salt effect parameter of $k_{\text{sl(c)c}} = 0.0993$, but the linear portion extrapolated to a water solubility value that was twice its normal value. The salt effect parameter was only 0.016 over the 0 to 3.6 ionic strength range and about 0.01 over the 11.8 to 18.8 ionic strength range. This is a complex system that deserves further analysis.

99 (19) Carbon dioxide + Ammonium sulfate [7783-20-2] + Sodium sulfate [7757-82-6] + Water

Rumpf and Maurer (56) measured the solubility of carbon dioxide in a solution that was 1 molal in $(\text{NH}_4)_2\text{SO}_4$ and 1 molal in Na_2SO_4 at six temperatures between 313 and 433 K over a total pressure range of 0.0084 to 9.67 MPa. Thus, the total ionic strength is about 6 mol kg^{-1} . Since we have only a single concentration it is not possible to calculate a salt effect parameter. The solubility data are probably quite good and are classed as tentative.

99 (20) Carbon dioxide + Ammonium nitrate [6484-52-2] + Sodium sulfate [7757-82-6] + Water

Onda, Sada, Kobayashi, Kito and Ito (37) measured the solubility of carbon dioxide in seven solutions of 0 to 2.81 mol L^{-1} total ionic strength in which the ionic strength ratio of ammonium nitrate and sodium sulfate was 1 at 298.15 K. The salt effect parameter is $k_{\text{sl(c)c}} = (0.0557 \pm 0.0009) \text{ L mol}^{-1}$. The value is 4.8 % less than one would calculate from the pure salt parameters. The value is classed as tentative.

99 (21) Carbon dioxide + Sodium chloride [7647-14-5] + Sodium sulfate [7757-82-6] + Water

Yasunishi, Tsuji and Sada (43) measured the solubility of carbon dioxide in six solutions with a total concentration of 0 to 2.49 mol L⁻¹ NaCl + Na₂SO₄ with NaCl salt mole fraction of 0, 0.25, 0.50, 0.75 and 1.00 at 298.15 K. The ionic strength fractions are NaCl/Na₂SO₄ = 0/1.0, 0.10/0.90, 0.25/0.75, 0.50/0.50 and 1.0/0. The ionic strength salt effect parameters are in the table below.

Table 53.

Ionic Strength Ratio NaCl/Na ₂ SO ₄	Ionic Strength Range I ₂ /mol L ⁻¹	Salt Effect Parameter k _{st(c)₂} /L mol ⁻¹	Std. Dev. about slope	Calc. Salt Effect Par.	Difference %
0/1.0	0 - 6.62	0.0988	0.0006	-	
0.10/0.90	0 - 4.36	0.0947	0.0013	0.0990	4.5
0.25/0.75	0 - 4.12	0.0950	0.0010	0.0993	4.5
0.50/0.50	0 - 3.11	0.0985	0.0018	0.0998	1.3
1.0/0	0 - 2.49	0.1007	0.0017	-	

The experimental result ranges from 4.5 to 1.3 % less than the result calculated assuming independent action of the electrolytes. The results are classed as tentative. See Figure 11A following section 100 (10).

99 (22) Carbon dioxide + Ammonium chloride [12125-02-9] + Sodium chloride [7647-14-5] + Sodium sulfate [7757-82-6] + Water

Yasunishi, Tsuji and Sada (43) measured the solubility of carbon dioxide in six solutions of five different mole ratios of the three salts; NH₄Cl/NaCl/Na₂SO₄ = 0/0.50/0.50, 0.125/0.50/0.375, 0.25/0.50/0.25, 0.325/0.50/0.125, and 0.50/0.50/0 at 298.15 K. Each was fitted to a lg L vs. c₂ line to obtain the salt effect parameters below. The calculated ionic strength salt effect parameters are based on the values for each salt in pure water. There is a small departure from additivity for the mixed electrolyte solutions.

Table 54.

Ionic Strength Ratio NH ₄ Cl/NaCl/Na ₂ SO ₄	Ionic Strength Range I ₂ /mol L ⁻¹	Salt Effect Parameter k _{st(c)₂} /L mol ⁻¹	Std. Dev. about slope	Calc. Salt Effect Par.	Difference %
0/0.250/0.750	0 - 4.12	0.0950	0.0010	0.0985	3.7
0.071/0.286/0.643	0 - 3.46	0.0901	0.0009	0.0933	3.6
0.167/0.333/0.500	0 - 3.73	0.0844	0.0012	0.0863	2.3
0.300/0.400/0.300	0 - 3.19	0.0724	0.0012	0.0765	5.7
0.500/0.500/0	0 - 3.45	0.0621	0.0015	0.0619	-0.3

99 (23) Carbon dioxide + Sodium thiosulfate [7772-98-7] + Water

Both Passauer (14) and Nahoczky (15) measured the solubility of carbon dioxide in saturated aqueous sodium thiosulfate, the first at 293 K the second at 288 K. The solubility measurements are classed tentative, but no salt effect parameters were calculated from the data because of uncertainty in the solubility of sodium thiosulfate and concern about the reliability of a salt effect parameter based on just one salt concentration.

99 (24) Carbon dioxide + Sodium nitrate [7631-99-4] + Water

The system was studied by Sechenov (5) at 288.35 K, Markham and Kobe (18) at 273.35 and 298.15 K, Yasunishi and Yoshida (42) at 288.15, 298.15 K and 308.15 K and by Gerecke (35) at five degree intervals between 288.15 and 333.15 K. In general the results accord well. Gerecke's results show by far the most scatter and largest standard deviation of the slope of lg L vs. c₂ plots. Salt effect parameters are in Table 55 (next page).

Gerecke (35) reports values at 293, 303, 313, 318 and 328 K in addition to his values above. His solubility values scatter much more than the data of the other workers and a simple straight line slope does not show the expected variation with temperature. The data are classed doubtful.

The values in [] in Table 55 (next page) are combined data sets and are recommended. The recommended salt effect parameters are (0.0874 ± 0.0010) at 288.2 K and (0.0777 ± 0.0002) at 298.15 K.

Table 55.

<i>T/K</i>	Concentration Range, <i>c</i> ₂ /mol L ⁻¹	Salt Effect Parameter <i>k</i> _{sc} /L mol ⁻¹	Reference
273.35	0 - 6.300	0.0989	MK (18)
288.15	0 - 4	0.0677	G (35)
	0.382 - 5.929	0.0847	YY (42)
288.35	0 - 7.356	0.0891	S (5)
[288.2	0 - 7.356	0.0874	(5) & (42)]
298.15	0 - 6.300	0.0770	MK (18)
	0 - 4	0.0677	G (35)
	0.382 - 7.256	0.0781	YY (42)
[298.15	0 - 7.256	0.0777	(18) & (42)]

333.15	0 - 4	0.0649	G (35)

**99 (25) Carbon dioxide + Phosphoric acid [7664-38-2]
+ Sodium dihydrogen phosphate [7558-80-7] + Water**

Van Slyke, Sendroy, Hastings and Neill (13) measured the solubility of carbon dioxide in 0.150 and 0.300 mol L⁻¹ H₃PO₄ and in mixtures of 0.0375 to 0.300 mol L⁻¹ NaH₂PO₄ and 0.011 to 0.030 mol L⁻¹ H₃PO₄ at 311.2 K. The solubility was corrected for the effect of phosphoric acid, which changed the solubility 0.3 % or less, and the corrected solubility treated as if only the sodium salt was present. The salt effect parameter for the NaH₂PO₄ alone was *k*_{sc} = (0.184 ± 0.005) L mol⁻¹. See section 19 (1) for the result for phosphoric acid.

99 (26) Carbon dioxide + Sodium formate [141-53-7] + Water

99 (27) Carbon dioxide + Sodium acetate [127-09-3] + Water

Gerecke (35) reports carbon dioxide solubility data between 0 and 4 mol L⁻¹ sodium formate and 0 and 2 mol L⁻¹ sodium acetate at five degree intervals between 288.15 and 333.15 K. The solubility of carbon dioxide in sodium formate shows salting in at concentration of 0.1, 0.2 and 0.5 mol L⁻¹, salting out at 1 and 2 mol L⁻¹ and salting in at 4 mol L⁻¹. A similar variation is observed in the sodium acetate solutions.

Both formate and acetate ions are the anions of weak acids and thus themselves bases. We would expect an apparent salting in because of the reaction of the basic anions with the acidic carbon dioxide. Reactions

contribute to the effect. We have not tried to analyze the data beyond the suggestion of an acid base interaction being responsible for the apparent salting in.

99 (28) Carbon dioxide + Sodium phenoxide [139-02-6] + Water

Kimura and Takeuchi (29) report the solubility of carbon dioxide in aqueous sodium phenoxide as functions of temperature, pressure and electrolyte concentration. The data show the effect of an acid base reaction between the acidic carbon dioxide and the basic phenoxide anion. At 293.15 K there is strong salting in at all concentrations between 0.805 and 3.04 mol L⁻¹ sodium phenoxide which is described by a salt effect parameter of -0.237, at 323.15 the salt effect parameter is -0.40. The salt effect parameters were calculated for the solubility values at 0.98/0.99 atm partial pressure carbon dioxide. The values are classed tentative.

99 (29) Carbon dioxide + Sodium 4-[[4-(dimethylamino)phenyl]azo]benzenesulfonic acid salt (Methyl orange) [547-58-0] + Water

Findlay and Shen (9) measured the solubility of carbon dioxide in dilute solutions of methyl orange at 298.15 K. The evaluator treated the solubility data at 122 - 124 kPa and obtained a salt effect parameter of -3.00 L mol⁻¹ for the 0.0101 to 0.0281 mol L⁻¹ methyl orange solutions with a standard deviation of the slope of 0.15. The methyl orange salts-in strongly. The result is classed tentative, but use with caution.

99 (30) Carbon dioxide + Lactic acid [50-21-5] + Sodium lactate [920-49-0] + Water

Van Slyke, Sendroy, Hastings and Neill (13) measured the solubility of carbon dioxide in 0.100 to 0.300 mol L⁻¹ lactic acid and in mixtures of 0.150 and 0.300 mol L⁻¹ sodium lactate and 0.100 to 0.300 mol L⁻¹ lactic acid at 311.2 K. The effect for the lactic acid is scattered and small. Its molar parameter is $k_{\text{acc}} = (0.006 \pm 0.006) \text{ L mol}^{-1}$. The lactic acid was assumed to have a negligible effect in the mixture and the data were treated as if sodium lactate alone was present. The resulting salt effect parameter is $k_{\text{acc}} = (0.125 \pm 0.006) \text{ mol L}^{-1}$. The sodium lactate salts out and the result is classed tentative.

99 (31) Carbon dioxide + Sodium monododecyl sulfuric acid ester (or SDS); [151-21-3] + Water

99 (32) Carbon dioxide + Sodium 1-heptylsulfonate (or SHSo); [22767-50-6] + Water

99 (33) Carbon dioxide + Sodium perfluoro-octanoate (or SPFO); [335-95-5] + Water

23 (4) Carbon dioxide + N,N,N-Trimethyl-1-hexadecanaminium bromide (or CTAB); [57-09-0] + Water

NOTE: This system belongs with the carbon number, 23. It is better considered here with other micelle forming solutions.

Ownby, Prapaitrakul and King (50) measured the solubility of carbon dioxide in the four systems listed above at either 298.2 or 299.2 K over a small pressure range. The solutions appear to obey Henry's law. At salt concentrations above the critical micelle concentration (CMC) the carbon dioxide is salted in, below the CMC the gas is salted out. The salt CMC's are: SDS 0.0081; SPFO 0.032; CTAB 0.00092; and SHSo 0.28 mol kg⁻¹. Only the sodium 1-heptyl sulfonate (SHSo) has a large enough CMC to see the salting out effect (Figure 8). Both the salting out and salting in parameter are given for the SHSo, and only salting in parameters are given for the other salts in the table below.

Table 56.

Salt	Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{acc}}/\text{kg mol}^{-1}$	Std Dev of Slope
SHSo	0.0 - 0.4	0.091	0.004
	0.6 - 1.2	-0.060	0.003
SDS	0.0 - 0.6	-0.116	0.006
SPFO	0.0 - 0.6	-0.164	0.007
CTAB	0.0 - 0.4	-0.179	0.008

Figure 8. Logarithm of carbon dioxide molality vs. salt molality. The four salts are sodium perfluoro-octanoate (SPFO), cetyltrimethylammonium bromide (CTAB), sodium dodecyl sulfate (SDS), and sodium 1-heptylsulfonate (SHSo). These salts are micelle forming substances. The carbon dioxide is "salted in" above the CMC (critical micelle concentration). Only one of the four salts (SHSo) has a large enough CMC to show the effect of salting out below the CMC salting in above the CMC.

99 (34) Carbon dioxide + Sodium trifluoroacetate [2923-18-4] + Water

Castellani and Berchiesi (62) report one solubility measurement of carbon dioxide in 19.0 mol kg⁻¹ sodium trifluoroacetate at 294.65 K and 0.936 atm of 0.0077 mol L⁻¹. The evaluator estimated a solubility of carbon dioxide in water under these conditions of 0.0353 mol L⁻¹. The two values give a salt effect parameter of $k_{\text{smc}} = 0.035$. The value is classed tentative, but use with caution.

100 (1) Carbon dioxide + Potassium chloride [7447-40-7] + Water

The system has been studied by Sechenov (5) at 288.35 K, by Geffcken (6) at 288.15 and 298.15 K, by Findlay and Shen (9) at 298.15 K, by Passauer (14) at 293.15 K, by Markham and Kobe (18) at 273.35, 298.15 and 313.15 K, Gerecke (35) at five degree intervals between 288.15 and 333.15 K, by Yasunishi and Yoshida (42) at 298.15 and 308.15 K, by Burmakina, Efanov, and Shnet (45) at 298.15 K and by He and Morse (57) at five temperatures between 273.15 and 363.15 K. Each workers data have been fitted to a linear $\lg L$ vs. c_2 line with the exception of He and Morse whose data was fitted to a linear $\lg m_1$ vs. m_2 line and Passauer (14), whose measurement in saturated aqueous potassium chloride, was not used. The concentration results are below.

Table 57.

T/K	KCl Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sc}}/\text{L mol}^{-1}$	Standard Deviation of Slope	Reference
273.35	0 - 3	0.0768	0.0017	MK (18)
288.15	0.423 - 1.058	0.0731	0.0022	Gf (6)
	0 - 1	0.0817	0.0012	G (35)
288.35	0.0 - 2.564	0.0935	0.0041	S (5)
298.15	0.423 - 1.058	0.0705	0.0029	Gf (6)
	0.247 - 1.000	0.0680	0.0052	FS (9)
	0.0 - 3.558	0.0622	0.0015	MK (18)
	0.0 - 2.0	0.0650	0.0029	G (35)
	0.498 - 4.131	0.0569	0.0015	YY (42)
[298.15	0 - 0.200	0.0755	0.0119	BES (45)
	0.0 - 2.0	0.0664	0.0009	all except (45)]
308.15	0 - 2	0.0694	0.0135	G (35)
	0.420 - 4.110	0.0567	0.0011	YY (42)
313.15	0 - 3	0.0597	0.0043	MK (18)
	0 - 2	0.0755	0.0134	G (35)
323.15	0 - 2	0.0776	0.0135	G (35)
333.15	0 - 2	0.0854	0.0214	G (35)

The value at 298.15 in [] is based on the 21 values from all papers between 0.0 and 2.0 mol L⁻¹ KCl. It is the only recommended value. A plot of all the data to 4.3 mol L⁻¹ KCl shows a small curvature at concentrations above 2.0 mol L⁻¹ KCl. Gerecke's value at 4.3 mol L⁻¹ is off from the pattern of the other data and is rejected. Burmakina *et al.* (45) made nine measurements in the 0 - 0.200 mol L⁻¹ KCl range. Measurements in dilute solutions are difficult and subject to large error [(49) and this volume preliminary material]. Their data scatters badly and their results were not included in the general average of 298.15 K data. The data of He and Morse (57) are treated separately below.

Table 58.

T/K	p_1/bar	KCl Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{smm}}/\text{kg mol}^{-1}$	Standard Deviation of Slope	Reference
273.35	1.049	0.1 - 3.51	0.0403	0.0037	HM (57)
298.15	0.954	0.1 - 4.0	0.0375	0.0072	HM (57)
323.15	0.865	0.1 - 5.0	0.0248	0.0015	HM (57)
348.15	0.611	0.1 - 5.0	0.0174	0.0019	HM (57)
363.15	0.305	0.1 - 5.0	0.0170	0.0013	HM (57)

The values appear to be slightly lower than expected from the other data on the system. They are classed as tentative.

Figure 9 shows logarithm of Bunsen coefficient vs. the potassium chloride concentration (ionic strength) at 288 and 298 K. Only the data of Gerecke (35) deviates significantly from the other data. The data of He and Morse (57), calculated as Bunsen coefficients from the author's data assuming ideal gas and Henry's law behavior, show more scatter than the other data.

Figure 9. Logarithm of Bunsen coefficient vs. potassium chloride concentration (ionic strength).

100 (2) Carbon dioxide + Hydrochloric acid [7647-01-0] + Potassium chloride [7447-40-7] + Water

Van Slyke, Sendroy, Hastings and Neill (13) measured the solubility of carbon dioxide in solutions that were 0.01 mol L^{-1} in HCl and 0 to 0.300 mol L^{-1} in KCl at 311.2 K . The very small concentration of HCl was assumed to have a negligible effect on salting out and the data were treated as if KCl alone was present. The result for the KCl is $k_{\text{acc}} = (0.0691 \pm 0.0032) \text{ mol L}^{-1}$ and it is classed tentative.

100 (3) Carbon dioxide + Calcium chloride [10043-52-4] + Potassium chloride [7447-40-7] + Water

Yasunishi, Tsuji and Sada (43) studied this system at 298.15 K and mole ratios of KCl/CaCl_2 of $0.0/1.00$, $0.25/0.75$, $0.50/0.50$, $0.75/0.25$ and $1.00/0.0$. As an ionic strength ratio the values are $0.0/1.00$, $0.10/0.90$, $0.25/0.75$, $0.50/0.50$ and $1.0/0$. The resulting salt effect parameters assuming a linear $\lg L$ vs. I_2 are shown in Table 59 (next page). The calculated values assume the pure KCl and pure CaCl_2 salt effect parameters are additive as the sum of the products of ionic strength fraction times the salt effect parameter for each electrolyte. See also Figure 11B following section 100 (10).

The pure KCl and CaCl_2 values in Table 59 do not agree well with values given earlier. Another problem is that the regression lines give solubility in water values that range from 1.4 to 4.1 % low. In spite of these problems, the pure salt effect parameters have been used to calculate the salt effect parameters for the mixtures and the results appear satisfactory. The data deserve a more detailed treatment than we can give it here. They are classed as tentative.

Table 59.

Ionic Strength Ratio KCl/CaCl ₂	Concentration Range $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{s(c)_e}/\text{L mol}^{-1}$	Salt Effect Parameter Calculated	Difference %
1.00/0.00	0.498 - 3.505	0.0605	-	-
0.50/0.50	0.429 - 3.501	0.0586	0.0588	0.3
0.25/0.75	0.512 - 3.401	0.0594	0.0580	2.3
0.10/0.90	0.426 - 3.233	0.0572	0.0574	0.4
0.00/1.00	0.558 - 3.801	0.0571	-	-

100 (4) Carbon dioxide + Sodium chloride [7647-14-5] + Potassium chloride [7447-40-7] + Water

Yasunishi, Tsuji and Sada (43) studied this system at 298.15 K and mole ratios of (same as ionic strength ratios) NaCl/KCl of 0.0/1.0, 0.25/0.75, 0.50/0.50, 0.75/0.25 and 1.0/0.0. The resulting salt effect parameters assuming a linear $\lg L$ vs. I_2 are below. The calculated values assume the pure NaCl and pure KCl salt effect parameters are additive as the sum of the products of mol fraction times the salt effect parameter for each electrolyte.

Table 60.

Ionic Strength Ratio NaCl/KCl	Concentration Range $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{s(c)_e}/\text{L mol}^{-1}$	Salt Effect Parameter Calculated	Difference %
1.00/0.00	0.498 - 3.505	0.0986	-	-
0.75/0.25	0.545 - 4.311	0.0873	0.0882	1.0
0.50/0.50	0.479 - 4.396	0.0766	0.0778	1.6
0.25/0.75	0.537 - 4.125	0.0677	0.0673	-0.6
0.00/1.00	0.498 - 4.131	0.0569	-	-

The mixed electrolyte systems appear to have no specific interaction within experimental error. The data are classed tentative. See Figure 11A following section 100 (10).

100 (5) Carbon dioxide + Calcium chloride [10043-52-4] + Sodium chloride [7647-14-5] + Potassium chloride [7447-40-7] + Water

The system was studied by Yasunishi, Tsuji and Sada (43) at 298.15 K and several ratios of CaCl₂/NaCl/KCl. The salt effect parameters are in the table below.

Table 61.

Ionic Strength Ratio CaCl ₂ /NaCl/KCl	Concentration Range $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{s(c)_e}/\text{L mol}^{-1}$	Salt Effect Parameter Calculated	Difference %
0.00/0.50/0.50	0.479 - 4.396	0.0766	0.0778	1.6
0.50/0.167/0.333	0.386 - 2.762	0.0643	0.0669	4.0
0.75/0.00/0.25	0.512 - 3.401	0.0580	0.0561	3.3

The calculated salt effect parameter is probably within experimental error of the measured parameter. The values are classed tentative.

100 (6) Carbon dioxide + Potassium bromide [7758-02-3] + Water

Three laboratories report data on the system. Sechenov (5) studied the system at 288.35 K, Geffcken (6) at 288.15 and 298.15 K and Gerecke (35) at ten temperatures between 288.15 and 333.15 K.

The data of both Sechenov and Geffcken at 288 K are linear in $\lg L$ vs. c_2 , but the slopes do not agree well. Gerecke's data shows salting in at 4 mol L⁻¹ KBr at temperatures of 298 K and above. Plots of Gerecke's data as $\lg L$ vs. c_2 are linear to either 0 - 1 or 0 - 2 mol L⁻¹ KBr. The slopes do not agree with the values of Sechenov and Geffcken. The salt effect parameter is not a regular increase or decrease with increasing temperature. Gerecke's data are classed doubtful.

The salt effect parameters of Sechenov and Geffcken and a sampling of Gerecke's values are below. Geffcken's values are preferred, but use with caution.

Table 62.

T/K	KBr Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sec}}/\text{L mol}^{-1}$	Standard Deviation of Slope	Reference
288.15	0.550 - 1.064	0.0635	0.0012	Gf (6)
	0.0 - 2.0	0.0499	0.0044	G (35)
288.35	0.0 - 4.228	0.0567	0.0017	S (5)
298.15	0.550 - 1.064	0.0672	0.0030	Gf (6)
	0.0 - 4.0	0.0074	0.0146	G (35)
	0.0 - 2.0	0.0394	0.0080	G (35)
	0.0 - 1.0	0.0602	0.0022	G (35)
303.15	0.0 - 1.0	0.0506	0.0016	G (35)
313.15	0.0 - 1.0	0.117	0.037	G (35)
323.15	0.0 - 1.0	0.150	0.002	G (35)
333.15	0.0 - 1.0	0.136	0.048	G (35)

100 (7) Carbon dioxide + Potassium iodide [7681-11-0] + Water

In addition to the same three workers (5, 6, 35) that report on the KBr systems, Onda Sada, Kobayashi, Kito and Ito (36) report carbon dioxide solubility measurements at 0, 1 and 2 mol L⁻¹ KI at 298.15 K and 0.1013 MPa, Passauer (14) reports a measurement in saturated aqueous KI at 293.15 K, and Vázquez, Chenlo, Pereira and Peaguda (64) report seven measurements between 0.241 and 1.687 mol L⁻¹ KI at 298.1 K and 0.1013 MPa. In an earlier paper (61) they report the solubility in water at the same temperature and pressure. Passauer's value was not used. At 298.15 K there is fair agreement among the results of Geffcken (6), Gerecke (35) and Onda *et al.* (36) to 2 mol L⁻¹ KI. The results are classed tentative. The data of Vázquez *et al.* (64) are about 7 % smaller than the other data for any given KI concentration and their data are classed doubtful. Their data shows a definite curvature which is emphasized more when the water value is used. See also Figure 10 (next page). The salt effect parameters are below.

Table 63.

T/K	KI Concentration Range, $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{sec}}/\text{L mol}^{-1}$	Standard Deviation of Slope	Reference
288.15	0.559 - 1.119	0.0624	0.0029	Gf (6)
288.35	0.0 - 5.767	0.0516	0.0027	S (5)
298.15	0.559 - 1.119	0.0540	0.0006	Gf (6)
	0.0 - 4.0	0.0208	0.0057	G (35)
	0.0 - 2.0	0.0453	0.0013	G (35)
	0.0 - 1.0	0.0483	0.0017	G (35)
	0.0 - 2.002	0.0520	0.0036	OSK (36)
	0.0 - 1.69	0.0505	0.0081	VCPP (64)
	0.24 - 1.69	0.0375	0.0040	VCPP (64)
	0.0 - 1.0	0.0541	0.0023	(6, 35, 36)
313.15	0.0 - 2.0	0.0581	0.0082	G (35)
323.15	0.0 - 2.0	0.0659	0.0083	G (35)
333.15	0.0 - 2.0	0.0830	0.0119	G (35)

Sechenov's data at 288.35 K are classed tentative although the salt effect parameter is smaller than expected from other data at 288 and 298 K. Gerecke's data at the higher temperatures shows a salting out effect that increases with temperature. This is contrary to normal expectations and the data should be used with caution.

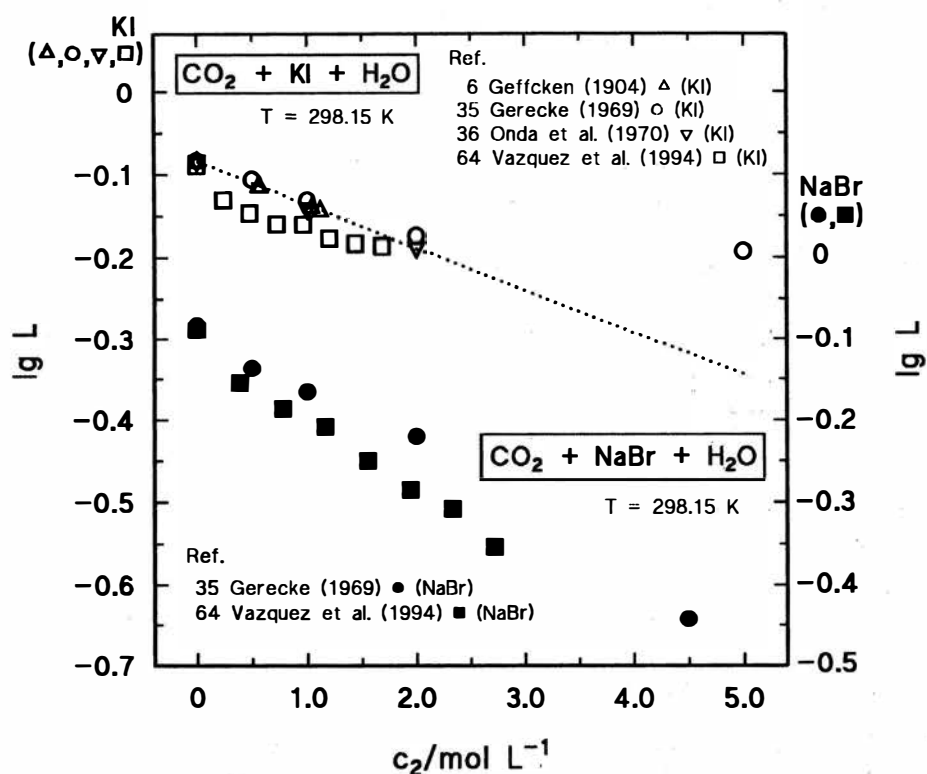

Figure 10. Logarithm of Ostwald coefficient vs. potassium iodide and sodium bromide concentrations.

100 (8) Carbon dioxide + Potassium sulfate [7778-80-5] + Water

Yasunishi and Yoshida (42) measured the solubility of carbon dioxide at four concentrations of potassium sulfate between 0.093 and 0.454 mol L⁻¹ (0.279 and 1.362 ionic strength) at 298.15 K. The salt effect parameter as a function of ionic strength is $k_{s(e)c} = (0.0777 \pm 0.0003)$ L mol⁻¹ and it is classed as tentative. Passauer (14) reports the carbon dioxide solubility in saturated aqueous potassium sulfate at 293.15 K. No salt effect parameter was calculated from his measurement.

He and Morse (57) measured the solubility of carbon dioxide in 0.01 to as high as 0.9 mol kg⁻¹ K₂SO₄ at five temperatures between 273.15 and 363.15 K. The carbon dioxide partial pressure was different at each temperature. They reported both salt and gas in molality. Ionic strength salt effect parameters in molality units from their data are in the table below. The values are classed tentative. Multiplication by three will put the salt effect parameters on a molal basis.

Table 64.

<i>T</i> /K	<i>p</i> ₁ /bar	K ₂ SO ₄ Molal Range, <i>m</i> ₂ /mol kg ⁻¹	Salt Effect Parameter <i>k</i> _{s(e)m} /kg mol ⁻¹	Standard Deviation of Slope	Reference
273.15	1.049	0.01 - 0.4	0.0734	0.0071	HM (57)
298.15	0.954	0.1 - 0.6	0.0568	0.0051	HM (57)
323.15	0.865	0.02 - 0.81	0.0377	0.0028	HM (57)
348.15	0.611	0.1 - 0.9	0.0260	0.0031	HM (57)
363.15	0.305	0.1 - 0.9	0.0226	0.0024	HM (57)

100 (9) Carbon dioxide + Potassium nitrate [7757-79-1] + Water

A number of workers have studied this system. Sechenov (4) at 288.35 K, Geffcken (6) at 288.15 and 298.15 K, Markham and Kobe (18) at 273.35, 298.15 and 313.15 K, Gerecke (35) at five degree intervals between 288.15 and 328.15 K and Yasunishi and Yoshida (42) at 298.15 and 308.15 K. The salt effect parameters obtained by finding the slope of lg *L* vs. *c*₂ plots of each workers data at each temperature are given in Table 65 (next page). The data are classed tentative, but the Markham and Kobe data are preferred.

Table 65.

323.15	0.0 - 2.0	0.0348	G (35)
328.15	0.0 - 2.0	0.0361	G (35)

100 (10) Carbon dioxide + Sodium chloride [7647-14-5] + Potassium nitrate [7757-79-1] + Water

Yasunishi, Tsuji and Sada (43) have studied this system at 298.15 K. They report the solubility of carbon dioxide in aqueous NaCl, KNO₃, and three mixed electrolyte solutions of mole fraction ratio NaCl/KNO₃ 0.25/0.75, 0.50/0.50 and 0.75/0.25. The salt effect parameters for the five solutions are given in Table 66 on the next page.

The calculated salt effect parameters assume the two electrolytes act independently. It is probably true within the experimental error of these experiments. The values are classed tentative. See Figure 11A.

Figure 11A. CO₂ + Binary salts + H₂O. A test of the additivity of salt effect parameters as a function of ionic strength fraction, 298.15 K.

In Figure 11 A systems from top to bottom are:

99 (21) $\text{CO}_2 + \text{Na}_2\text{SO}_4 + \text{NaCl} + \text{H}_2\text{O}$
 100 (4) $\text{CO}_2 + \text{KCl} + \text{NaCl} + \text{H}_2\text{O}$
 100 (10) $\text{CO}_2 + \text{KNO}_3 + \text{NaCl} + \text{H}_2\text{O}$
 99 (5) $\text{CO}_2 + \text{NH}_4\text{Cl} + \text{NaCl} + \text{H}_2\text{O}$
 99 (4) $\text{CO}_2 + \text{HNO}_3 + \text{NaCl} + \text{H}_2\text{O}$

Table 66.

Ionic Strength Ratio NaCl/KNO ₃	Concentration Range $c_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{\text{acc}}/\text{L mol}^{-1}$	Salt Effect Parameter Calculated	Difference %
0.00/1.00	0.288 - 1.630	0.0419	-	-
0.25/0.75	0.298 - 1.664	0.0576	0.0564	2.1
0.50/0.50	0.289 - 2.173	0.0698	0.0708	1.4
0.75/0.25	0.264 - 1.723	0.0838	0.0853	1.8
1.00/0.00	0.455 - 3.400	0.0997	-	-

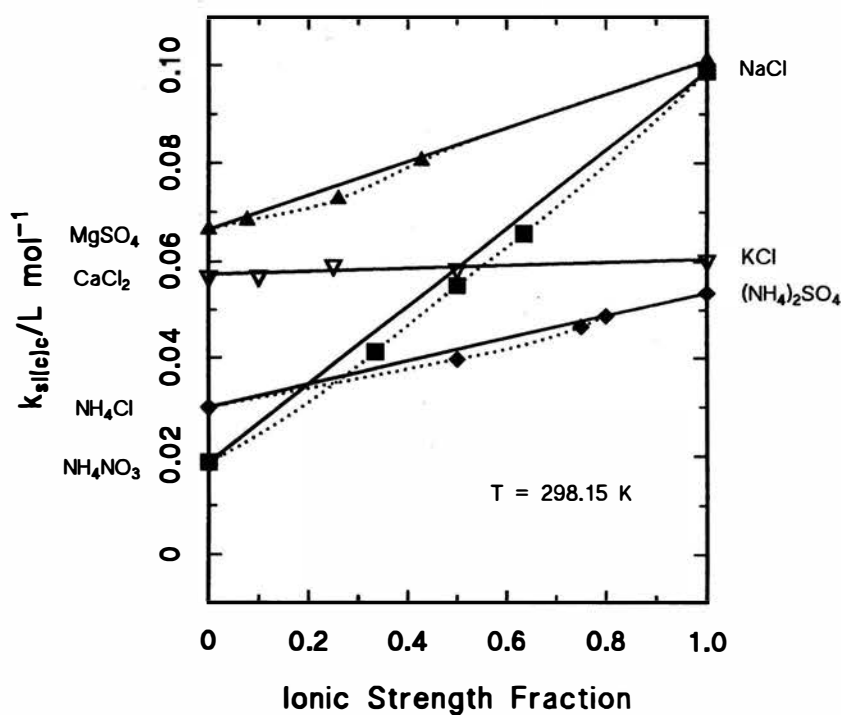

Figure 11B. $\text{CO}_2 + \text{Binary salts} + \text{H}_2\text{O}$. A test of the additivity of salt effect parameters as a function of ionic strength fraction, 298.15 K.

Systems from right top to bottom:

99 (7) $\text{CO}_2 + \text{MgSO}_4 + \text{NaCl} + \text{H}_2\text{O}$
 99 (6) $\text{CO}_2 + \text{NH}_4\text{NO}_3 + \text{NaCl} + \text{H}_2\text{O}$
 100 (3) $\text{CO}_2 + \text{CaCl}_2 + \text{KCl} + \text{H}_2\text{O}$
 18 (5) $\text{CO}_2 + \text{NH}_4\text{Cl} + (\text{NH}_4)_2\text{SO}_4 + \text{H}_2\text{O}$

100 (11) Carbon dioxide + Magnesium sulfate [7487-88-9] + Sodium chloride [7647-14-5] + Potassium nitrate [7757-79-1] + Water

The system was studied by Yasunishi, Tsuji and Sada (43) at 298.15 K. The results are in Table 67 (next page).

Table 67.

Ionic Strength Ratio $\text{MgSO}_4/\text{NaCl}/\text{KNO}_3$	Ionic Strength Range $I_2/\text{mol L}^{-1}$	Salt Effect Parameter $k_{s(\text{c})}/\text{L mol}^{-1}$	Salt Effect Parameter Calculated	Difference %
0.80/0.20/0.0	0 - 5.46	0.0725	0.0736	1.5
0.571/0.286/0.143	0 - 3.96	0.0667	0.0729	9.3
0.0/0.50/0.50	0 - 2.17	0.0707	0.0712	0.70

The results indicate additivity of salt effects when two salts are present, but some specific effect when three salts are present. The standard errors about the regression line are 0.0004, 0.0005 and 0.0014, respectively for the three values in the order they appear in the table above. The results are classed as tentative.

100 (12) Carbon dioxide + Potassium dihydrogen phosphate [7778-77-0] + Water

Gerecke (35) studied the system at five degree intervals between 288.15 and 333.15 K at electrolyte concentrations of 0, 0.25, 0.5 and 1 mol L⁻¹. We did not try to calculate an ionic strength for the KH₂PO₄ electrolyte. The CO₂ solubility at 1.0 mol L⁻¹ electrolyte shows a lower solubility than expected from the behavior shown at lower electrolyte concentrations. Salt effect parameters based on the solubilities at 0.0, 0.25 and 0.50 mol L⁻¹ are given below:

<i>T</i> /K	288.15	298.15	313.15	323.15	333.15
$k_{\text{acc}}/\text{L mol}^{-1}$	0.192	0.175	0.206	0.204	0.239
Std. dev. slope	0.013	0.010	0.009	0.035	0.008

The salt effect parameter shows several unusual effects. It is larger than seen for other electrolytes. There is no indication of an acid-base interaction between the carbon dioxide and the anions present in solution. If the electrolyte is mainly K⁺, H⁺ and HPO₄²⁻ the salt effect parameters need be divided by 3 to put them on an ionic strength basis. The values would then be consistent with values for other electrolytes. The temperature coefficient of the salt effect parameter is doubtful until confirmed by other work.

100 (13) Carbon dioxide + Phosphoric acid [7664-38-2] + Potassium dihydrogenphosphate [7778-77-0] + Water

Van Slyke, Sendroy, Hastings and Neill (13) measured the solubility of carbon dioxide in 0.150 and 0.300 mol L⁻¹ H₃PO₄ and in mixtures of 0 to 0.300 mol L⁻¹ KH₂PO₄ and 0.015 to 0.030 mol L⁻¹ H₃PO₄ at 311.2 K. The phosphoric acid data were analysed separately, see section 19 (1). In the mixed system the solubility was corrected assuming the phosphoric acid acted independently. The correction was 0.3 % or less. The corrected solubility was treated as if the potassium dihydrogen phosphate was present alone. The resulting salt effect parameter is $k_{\text{acc}} = (0.151 \pm 0.003) \text{ mol L}^{-1}$. See section 99 (25) for the treatment of the sodium salt system.

100 (14) Carbon dioxide + β -D-Fructofuranosyl- α -D-glucoopyranoside (sucrose) [57-50-1] + Potassium dihydrogenphosphate [7778-77-0] + Water

de Molineri, de Cozzitorti, Sosa and Katz (51) measured the solubility of carbon dioxide in five sucrose solutions from 5 to 15 mass fraction sucrose each containing 0 to 15 mass fraction potassium dihydrogen phosphate at temperatures of 288.15, 298.15 and 308.15 K. The evaluator calculated the salt effect parameters in Table 68 (next page). The lg *L* vs. *m*₃ plots showed a small concave curvature and extrapolated to a carbon dioxide solubility in the aqueous sucrose solutions that was usually about 1 % low.

There are small, but consistent increases in the salt effect parameter with increasing temperature, and decreases in the parameter with increasing sucrose content. It is interesting to compare these results with the results of the aqueous KH₂PO₄, System 100 (12) above. The results from the aqueous sucrose solutions would represent the sucrose + water system, but no calculations were made for the system.

100 (15) Carbon dioxide + Potassium hydrogen oxalate [127-95-7] + Water

Van Slyke, Sendroy, Hastings and Neill (13) measured the solubility of carbon dioxide in 0.300 and 0.600 mol L⁻¹ KHC₂O₄ at 311.2 K. The molar salt effect parameter is $k_{\text{acc}} = (0.0683 \pm 0.0003) \text{ mol L}^{-1}$ and is classed tentative.

Table 68.

T/K	Sucrose $10^2 w_2$	KH_2PO_4 Molality Range, $m_2/\text{mol kg}^{-1}$	Salt Effect Parameter $k_{\text{acc}}/\text{kg mol}^{-1}$	Std. Dev. of slope
288.15	5	0 - 1.378	0.1299	0.0029
298.15	5	0 - 1.378	0.1305	0.0028
308.15	5	0 - 1.378	0.1310	0.0034
288.15	7.5	0 - 1.422	0.1263	0.0034
298.15	7.5	0 - 1.422	0.1284	0.0026
308.15	7.5	0 - 1.422	0.1285	0.0033
288.15	10	0 - 1.469	0.1257	0.0027
298.15	10	0 - 1.469	0.1269	0.0026
308.15	10	0 - 1.469	0.1270	0.0034
288.15	12.5	0 - 1.520	0.1245	0.0030
298.15	12.5	0 - 1.520	0.1257	0.0026
308.15	12.5	0 - 1.520	0.1263	0.0035
288.15	15	0 - 1.575	0.1236	0.0028
298.15	15	0 - 1.575	0.1259	0.0028
308.15	15	0 - 1.575	0.1263	0.0035

100 (16) Carbon dioxide + Lactic acid [50-21-5] + Potassium lactate [996-31-6] + Water

Van Slyke, Sendroy, Hastings and Neill (13) measured the solubility of carbon dioxide in 0.150 and 0.300 mol L⁻¹ lactic acid and in mixtures of 0.150 and 0.300 mol L⁻¹ potassium lactate and 0.100 to 0.300 mol L⁻¹ lactic acid at 311.2 K. The lactic acid alone shows a small and scattered effect (see section 99 (30)) and is considered to contribute negligible effect in the mixture. The data were treated as if potassium lactate alone was present. The result is $k_{\text{acc}} = (0.0959 \pm 0.0004)$ mol L⁻¹. The value is classed tentative.

100 (17) Carbon dioxide + Potassium thiocyanate [333-20-0] + Water

The system was studied by Sechenov (5) at 288.35 K in water and three aqueous solutions to over 10 mol L⁻¹ KSCN. The salt effect parameter, $k_{\text{acc}} = (0.041 \pm 0.03)$ L mol⁻¹, is classed tentative.

100 (18) Carbon dioxide + Potassium aluminum sulfate [10043-67-1] + Water

Only Rosenthal (24b) reports measurements on this system, and he reports on only one dilute solution at 293.15 K. The salt effect parameter has been calculated on both a concentration and ionic strength basis. The values are: $k_{\text{acc}} = 0.84$ and $k_{\text{acc}(c)} = 0.094$. The values are classed as tentative. Ionic strength was calculated assuming 100 % dissociation into potassium, aluminum and sulfate ions.

101 (1) Carbon dioxide + Rubidium chloride [7791-11-9] + Water**102 (1) Carbon dioxide + Cesium chloride [7647-17-8] + Water**

Geffcken (6) measured the solubility of carbon dioxide in both RbCl and CsCl aqueous solutions at temperatures of 288.15 and 298.15 K. Gerecke (35) measured the solubility of carbon dioxide in aqueous solutions of CsCl at temperatures of 288.15, 293.15, 298.15 and 303.15 K at concentrations up to 2 mol L⁻¹. The salt effect parameters from these data are:

Table 69.

T/K	Electrolyte	No. of Detn.	Concentration Range $c_2/\text{L mol}^{-1}$	Salt Effect Parameter $k_{\text{acc}}/\text{L mol}^{-1}$	Reference
288.15	RbCl	4	0 - 1.012	0.060	Gf (6)
298.15	RbCl	4	0 - 0.55	0.058	Gf (6)
288.15	CsCl	2	0 - 0.55	0.045	Gf (6)
		4	0 - 2	0.036	G (35)
293.15	CsCl	4	0 - 2	0.030	G (35)
298.15	CsCl	2	0 - 0.55	0.044	Gf (6)
		4	0 - 2	0.032	G (35)
303.15	CsCl	4	0 - 2	0.031	G (35)

The CsCl salt effect parameters at 288.15 and 298.15 K from the two papers show fair agreement considering the small effect and the fact that all the Geffcken (6) measurements were made at low electrolyte concentrations. The evaluator has a slight preference for the results of Gerecke (35) except for the 293 K value which appears to be too small.

MISCELLANEOUS

The papers of Passauer (14), Nahoczky (15) and Kobe and Williams (16) contain a number of measurements in just one electrolyte solution for each system studied. A number of these have already been cited under the appropriate system. Other systems, for which these papers are the only data, are listed below.

Both Passauer (14) and Nahoczky (15) made measurements in water and in electrolyte solutions at or near saturation. They did not give an electrolyte saturation concentration, although Nahoczky (15) did give the saturated solution density. The evaluator did calculate a few salt effect parameters based on the carbon dioxide solubility in water and in the saturated salt solution using handbook values of the salt solubility. The values appear reasonable and it would seem that the data have some value. The systems not referenced earlier are listed below. However, no salt effect parameters are given because of uncertainty in the electrolyte solubility and a hesitation not to give salt effect parameters based on only one salt concentration.

The work of Kobe and Williams (16) is more complete. They did not work at electrolyte saturation, and they give the salt mass % composition. Salt effect parameters were calculated using *International Critical Table* densities except for mixed electrolyte solutions.

Passauer (14). Solubilities measured at or near salt saturation at 293 K and one atm.

- 33 (3) Carbon dioxide + Zinc iodide [10139-47-6] + Water
- 37 (1) Carbon dioxide + Silver nitrate [[7761-88-8] + Water
- 41 (5) Carbon dioxide + Iron (II) chloride [7758-94-3] + Water
- 96 (3) Carbon dioxide + Barium iodide [13718-50-8] + Water
- 99 (35) Carbon dioxide + Sodium nitrite [7632-00-0] + Water
- 99 (36) Carbon dioxide + Sodium hydrogen carbonate [144-55-8] + Water
- 99 (37) Carbon dioxide + Sodium dichromate [10588-01-9] + Water

Nahoczky (15). Solubilities measured at or near salt saturation at 288 K and one atm.

Solution densities were given.

- 48 (1) Carbon dioxide + Manganese sulfate [7785-87-7] + Water
- 52 (1) Carbon dioxide + Ammonium molybdate [12027-67-7]
- 93 (4) Carbon dioxide + 1/5 ethanol [64-17-5] + Magnesium sulfate [7487-88-9] + Water
- 99 (38) Carbon dioxide + 1/2 Magnesium chloride [7786-30-3] + 1/2 Sodium chloride [7647-14-5] + Water
- 99 (39) Carbon dioxide + 1/2 Magnesium sulfate [7487-88-9] + 1/2 Sodium chloride [7647-14-5] + Water
- 99 (40) Carbon dioxide + 1/3 Manganese sulfate [7785-87-7] + 1/3 Magnesium chloride [7786-30-3] + Sodium chloride [7647-14-5] + Water
- 99 (41) Carbon dioxide + 1/3 Manganese sulfate [7785-87-7] + 1/3 Magnesium sulfate [7487-88-9] + 1/3 Sodium chloride [7647-14-5] + Water
- 99 (42) Carbon dioxide + 1/2 Glycerine [56-81-5] + Sodium thiosulfate [7772-98-7] + Water
- 99 (43) Carbon dioxide + 1/2 Magnesium sulfate [7487-88-9] + 1/2 Sodium thiosulfate [7772-98-7] + Water
- 100 (19) Carbon dioxide + Potassium oxalate [583-52-8] + Water
- 100 (20) Carbon dioxide + Potassium ferrocyanide [13746-66-2] + Water
- 100 (21) Carbon dioxide + Potassium dichromate [7778-50-9] + Water

Kobe and Williams (16). Solubilities measured at one stated concentration at 298.15 K and one atm pressure.

99 (44) Carbon dioxide + Sulfuric acid [7664-93-9] + Sodium chloride [7647-14-5] + Water

The aqueous solution was 5 mass % H_2SO_4 (0.680 mol kg^{-1}) and 20 mass % NaCl (4.562 mol kg^{-1}). The molal ionic strength salt effect parameter assuming complete dissociation of the acid is $k_{\text{sl}(m)_c} = 0.0605$.

99 (45) Carbon dioxide + *ortho*-Phosphoric acid [7664-38-2] + Trisodium phosphate [7601-54-9] + Water

The aqueous solution was 7 mass % (0.861 mol kg^{-1}) H_3PO_4 and 10 mass % (0.735 mol kg^{-1}) Na_3PO_4 . The molal salt effect parameter is $k_{\text{mc}} = 0.293$.

99 (46) Carbon dioxide + Aerosol OT [577-11-7] + Water

99 (47) Carbon dioxide + Teepol CH 53 [50642-03-0] + Water

Gjaldbæk (24a) measured the solubility of carbon dioxide in Aerosol OT, and Rosenthal (24b) in a single dilute Teepol - water mixture. The values are classed tentative as there are no other data with which to compare them.

^b Henry's law constant K _H is defined as the amount of CO ₂ (mol) dissolved in 1 L of solvent under a partial pressure of 1 atm of CO ₂ .					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The principle of the experimental method was to transfer a known amount of CO ₂ into a gold-plated copper cylinder containing a known volume of solvent, to stir at constant temperature until equilibrium had been attained, and to measure the equilibrium pressure with the aid of a sensitive diaphragm. The latter was used as a null-detector, the pressure within the solubility vessel being balanced against an external pressure of N ₂ . The details are given in the source, and also in Ref. 1.			SOURCE AND PURITY OF MATERIALS: (1) Prepared by vaporizing the commercial solid CO ₂ and passing the gas through anhydrous Mg(ClO ₄) ₂ . (2) Not specified. (3) Not specified.		
			ESTIMATED ERROR: $\delta T/K = \pm 0.01$ (authors) $\delta P/mmHg = \pm 0.1$ (authors) $\delta K_H/K_H = \pm 0.01$ (authors)

		AUXILIARY INFORMATION																																																	
		METHOD/APPARATUS/PROCEDURE: Two procedures were used for saturating solutions with CO ₂ : <u>Saturation by bubbling (B).</u> The solution was placed in the saturating tube, the lower end of which was connected through a wash bottle with a Kipp CO ₂ generator. The tube and wash bottle were immersed in a constant temperature bath. CO ₂ gas was bubbled through it rapidly for 30 minutes. The wash bottle was replaced by a mercury reservoir and the free gas was driven completely out of the saturating tube by admitting mercury underneath the solution. The CO ₂ contents of the solutions were determined in the manometric gas apparatus (Refs 1 and 2). <u>Saturation in rotating tonometer (T).</u> The technique used was that described by Austin et al. (Ref. 3). Both procedures gave identical results with solutions of acids.	SOURCE AND PURITY OF MATERIALS: (1) From a Kipp CO ₂ generator. (2) Not specified. (3) Distilled. AUXILIARY INFORMATION																																																																																																																					
METHOD/APPARATUS/PROCEDURE: Either pure CO ₂ gas or CO ₂ -N ₂ mixtures were used in the experiments to maintain a constant $P(\text{CO}_2)$. The CO ₂ -N ₂ mixtures were made by pumping predetermined amounts of CO ₂ and N ₂ into a gas tank and their composition was verified by gas chromatography. CO ₂ or CO ₂ -N ₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min ⁻¹ . The mole fraction of CO ₂ in the CO ₂ -N ₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph.	SOURCE AND PURITY OF MATERIALS: (1) Commercial; purity 99.9 %. (2) Hydrochloric acid solutions were prepared by diluting concentrated HCl and standardizing the solution by titration. HCl was analytical reagent-grade which met ACS specifications. (3) 18 M Ω water obtained from a Milli-Q Super-Q water system. ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta m_1/m_1 = \pm 0.012$ $\delta \gamma_1/\gamma_1 = \pm 0.04$ REFERENCES:

<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The principle of the Ostwald method was used in which the gas is agitated with a measured quantity of gas-free liquid and the decrease in volume of solution-saturated gas is measured in a burette over mercury. The pressure was adjusted to yield one atmosphere partial pressure of carbon dioxide. The volume of gas was reduced to 0°C by the ideal gas law. Experiments were conducted to show that the agitation did not cause supersaturation.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Commercial cylinder, 99.8 % pure.</p> <p>(2) Baker, cp analyzed (ACS).</p> <p>(3) Distilled.</p> <p>ESTIMATED ERROR:</p> <p>$\delta T/K = \pm 0.03$ (authors), $\delta \alpha/\alpha, \delta S/S = \pm 0.002$ (authors).</p> <p>REFERENCES:</p> <p>1. ^a Calculated by the compiler. Concentration estimated from 25 °C Handbook data. ^b w_2 = mass fraction of H ₂ SO ₄ in solvent. ^c α = Bunsen coefficient [cm ³ (STP) cm ⁻³ atm ⁻¹].						
AUXILIARY INFORMATION						
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:			
Setchenow based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.			(1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.			
			ESTIMATED ERROR:			
			The author makes a qualitative statement that the results are good to the second decimal.

AUXILIARY INFORMATION																																																																																							
METHOD/APPARATUS/PROCEDURE: The principle of the Ostwald method was used in which the gas is agitated with a measured quantity of gas-free liquid and the decrease in volume of solution-saturated gas is measured in a burette over mercury. The pressure was adjusted to yield one atmosphere partial pressure of carbon dioxide. The volume of gas was reduced to 0°C by the ideal gas law. Experiments were conducted to show that the agitation did not cause super-saturation.	SOURCE AND PURITY OF MATERIALS: (1) Commercial cylinder, 99.8 % pure. (2) Baker, cp analyzed (ACS). (3) Distilled.

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: Solution was made up by weight. Concentration of solution was verified by measuring the density. (Density was not reported in paper.) A measured volume of gas was brought into contact with a measured quantity of gas-free solvent. Equilibrium was established by agitation using a magnetic stirrer. The volume of remaining gas was measured. The amount of gas absorbed was estimated from change in volume of gas. Details in original paper.			SOURCE AND PURITY OF MATERIALS: (1) From commercial cylinder. Purity 99.8 %. (2) Analytical grade. (3) Distilled and degassed.

		AUXILIARY INFORMATION																																							
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled. ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal. REFERENCES: 1. Setchenow, J. <i>Akad. Nauk. SSSR Mem. Acad. imp. Sci. St. Petersburg</i> <u>1887</u> , 35, [Ser. No. 7], 1-59.

<p>AUXILIARY INFORMATION</p>																																																																										
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref.1.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).</p> <p>(2) DDR pro analysis grade by DDR Standard TGL 5021.</p> <p>(3) Double distilled.</p> <p>ESTIMATED ERROR:</p> <p>Not given.</p> <p>REFERENCES:</p> <p>1. Gerecke, J.; Bittrich, H.J. <i>Wiss. Z. Tech. Hochsch. Chem. "Carl Schorlemmer" Leuna-Merseburg</i> <u>1971</u>, 13(2), 115-22.</p>

	250	30.20
	500	29.15
	1000	28.15

^a Data taken from a graph by compiler.

^b c_2 = concentration of NH₄Cl

^c c_1 = concentration of CO₂

AUXILIARY INFORMATION**METHOD/APPARATUS/PROCEDURE:**

Attainment of the equilibrium was checked by the constancy of CO₂ content in 3-5 subsequent samples of gas after saturation of the solution. The concentration of carbon dioxide was determined by titration.

SOURCE AND PURITY OF MATERIALS:

- (1) Source not given. Before contacting with water solutions CO₂ was allowed to pass through the vessels with NaHCO₃, glass beads, glass wool and distilled water.
- (2) Nothing specified.
- (3) Distilled.

ESTIMATED ERROR:

$$\delta c_1/c_1 = \pm 0.06 - 0.2 \%$$

$$\delta T/K = \pm 0.05$$

REFERENCES:

COMPONENTS: (1) Carbon dioxide; CO ₂ ; [124-38-9] (2) Ammonium chloride; NH ₄ Cl; [12125-02-9] (3) Water; H ₂ O; [7732-18-5]	ORIGINAL MEASUREMENTS: Rumpf, B.; Nicolaisen, H.; Maurer, G. <i>Ber. Bunsenges. Phys. Chem.</i> <u>1994</u> , 98, 1077-81.
VARIABLES: $T/K = 313.14 - 433.10$ $p/\text{MPa} = 0.482 - 9.692$ $m_2/\text{mol kg}^{-1} = \text{near } 4.00 \text{ and } 6.00$	PREPARED BY: Pirketta Scharlin
EXPERIMENTAL VALUES: <p>The authors used Pitzer's semiempirical model to correlate the data. The model has been described in detail in Ref. 1. The dissociation of CO₂ can be neglected at the concentrations here. The system was treated as containing a non-dissociating gas, G and a completely dissociating electrolyte, MX. A temperature dependent interaction parameter, $B^{\circ}_{\text{CO}_2, \text{NH}_4\text{Cl}}$, and a temperature independent interaction parameter, $\Gamma_{\text{CO}_2, \text{NH}_4\text{Cl}, \text{NH}_4\text{Cl}}$, were derived from the experimental data.</p> <p>For the CO₂ + NH₄Cl + H₂O system the values are:</p> $B^{\circ}_{\text{CO}_2, \text{NH}_4\text{Cl}} = 0.2834 - 123.27(T/K)^{-1} + 1551.29(T/K)^{-2} + 3543 \cdot 10^3(T/K)^{-3}$ <p>and $\Gamma_{\text{CO}_2, \text{NH}_4\text{Cl}, \text{NH}_4\text{Cl}} = -0.0010$.</p> <p>The interaction parameters were also predicted from earlier measurements on the solubility of CO₂ in aqueous solutions of Na₂SO₄, (NH₄)₂SO₄ (Ref 1.) and NaCl (Ref. 2). The predicted values are:</p> $B^{\circ}_{\text{CO}_2, \text{NH}_4\text{Cl}} = 0.4206 - 187.48(T/K)^{-1} + 691.287(T/K)^{-2} + 6312 \cdot 10^3(T/K)^{-3}$ <p>and $\Gamma_{\text{CO}_2, \text{NH}_4\text{Cl}, \text{NH}_4\text{Cl}} = -0.0035$.</p> <p style="text-align: right;">(continued on the next page)</p>	
AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: <p>The experimental equipment has been described in Ref. 1. It consists of a high pressure optical cell, thermostat, magnetic stirrer, thermocouples and Pt resistance thermometer, pressure transducers and tanks for aqueous solutions, rinse water and solute gas.</p> <p>The thermostated about 30 mL high pressure optical cell is filled with carbon dioxide. Pressure and temperature of the gas are measured after equilibration. A known amount of aqueous solvent is added which is slightly greater than that needed to completely dissolve the gas. The pressure in the cell is reduced stepwise by removing very small amounts of the liquid until the first stable bubble appears.</p> <p>The mass of carbon dioxide is calculated from the Bender equation (3). The volume of the cell is known within 0.06 mL. The solvent density is from the literature.</p>	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Messer Griesheim, Ludwigshafen, > 99.995 mol %, used as received. (2) Ammonium chloride. Riedel de Haen AG, Seelze, > 99.5 mass %. Degassed and dried under vacuum. (3) Water. Deionized and degassed by vacuum distillation.
ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta p/p < \pm 0.04$ (at p up to 6 MPa) $\delta p/p < \pm 0.05$ (at higher pressures)

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref.1.		SOURCE AND PURITY OF MATERIALS: (1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author). (2) DDR pro analysis grade by DDR Standard TGL 5021. (3) Double distilled.		
		ESTIMATED ERROR: Not given.

		AUXILIARY INFORMATION																							
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled. ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal. REFERENCES: 1. Setchenow, J. Akad. Nauk. SSSR Mem. Acad. Imp. Sci. St. Petersburg 1887, 35, [Ser. No. 7], 1-59.

<p>AUXILIARY INFORMATION</p>											
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The apparatus is a modification of one used in earlier work (1). It consists of a high pressure optical cell, thermostat, magnetic stirrer, thermocouples and Pt resistance thermometer, pressure transducers and tanks for aqueous solutions, rinse water and solute gas.</p> <p>The thermostated about 30 mL high pressure optical cell is filled with carbon dioxide. Pressure and temperature of the gas are measured after equilibration. A known amount of aqueous solvent is added which is slightly greater than that needed to completely dissolve the gas. The pressure in the cell is reduced stepwise by removing very small amounts of the liquid until the first stable bubble appears.</p> <p>The mass of carbon dioxide is calculated from the Bender equation (2). The volume of the cell is known within 0.06 mL. The solvent density is from the literature.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Carbon dioxide. Messer Griesheim, Ludwigshafen, > 99.995 mol %, used as received.</p> <p>(2) Ammonium sulfate. Merck GmbH, Darmstadt, > 99.5 mass %. Degassed and dried under vacuum.</p> <p>(3) Water. Deionized and degassed by vacuum distillation.</p> <p>ESTIMATED ERROR:</p> $\delta T/K = \pm 0.1$ $\delta m_2/m_2 = \pm 0.003$ $\delta m_1/m_1 = \pm 0.01 \text{ to } 0.03$ <p>REFERENCES:</p> <p>1. AUXILIARY INFORMATION																																																																																																										
METHOD/APPARATUS/PROCEDURE: Volumetric apparatus with multibulb buret and magnetic stirrer. Amount of solution and gas absorbed determined volumetrically. Partial pressure determined from total pressure and vapor pressure of solution. The vapor pressure of the mixed salt solution estimated by the method of Robinson and Bower (1) from corresponding data for each component salt solution. Apparatus similar to that described in Ref. 2.	SOURCE AND PURITY OF MATERIALS: (1) Extra pure grade, purity 99.96 mole %. (2,3) Reagent grade. (4) Deionized. ESTIMATED ERROR: $\delta T/K = \pm 0.05;$ $\delta L = \pm 1 \%$

AUXILIARY INFORMATION																																									
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.																																								
ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref.1.		(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).		
		(2) DDR pro analysis grade by DDR Standard TGL 5021.		
		(3) Double distilled.		
		ESTIMATED ERROR:		
		Not given.

AUXILIARY INFORMATION																																																																																																					
METHOD/APPARATUS/PROCEDURE: Volumetric method. The apparatus is described in detail in the source. The CO ₂ was purified in the line and sublimed into the system. Mercury levels were read with a cathetometer to ± 0.05 mm. Atmospheric pressures were read to ± 0.1 mm with a mercury barometer and were corrected to 0 °C. The volumes determined were reproducible to ± 0.02 mL.	SOURCE AND PURITY OF MATERIALS: (1) Commercial. Purity 99.9 %. (2,3) Fisher Certified Reagents. Purity better than 99.3 %. (4) Purified. Source not specified. (5) Conductivity water, distilled from a quartz still. Conductivity less than $1 \times 10^{-7} \Omega^{-1} m^{-1}$.

					7	35.7	6.0	29.7

^a The common name of the electrolyte is diammonium citrate.

^b Added by the compiler. The Kelvin temperatures are not intended to represent an accuracy, but to reproduce the Fahrenheit temperatures.

^c The pH given for water (c₂/mol L⁻¹ = 0) means pH of water saturated with carbon dioxide. According to the author the measurements showed that saturating water with CO₂ under the ambient barometric pressure in the temperature range of 80 to 140 °F yielded a pH of 4.2 ± 0.1.

The ammonium citrate solutions of certain pH's were prepared as follows: At pH 4 the solution was prepared from an equimolar mixture of citric acid and diammonium citrate to contain 11.1 g/L of monoammonium citrate, and its pH was adjusted upward to pH 4 by adding ammonia. At pH 5 the solution was primarily diammonium citrate and was prepared by dissolving 12 g of diammonium citrate per liter. At pH 6 and at pH 7 ammonia was added to the pH 5 solution. At pH 7 the salt was in the form of triammonium citrate. All solutions were initially prepared to contain 12 g diammonium citrate per liter (0.053 mol L⁻¹).

^d The values for the solubility of CO₂ in water are at a total pressure of 1 atm (101.3 kPa). The carbon dioxide in ammonium citrate solutions was measured at a barometric pressure of 730 mmHg (0.960 atm or 97.3 kPa).

The author distinguished between fixed CO₂, assumed to be in the form of bicarbonate and carbonate ion, and unfixed CO₂, assumed to be in the form of CO₂(aq) and H₂CO₃(aq).

AUXILIARY INFORMATION																											
METHOD/APPARATUS/PROCEDURE: <p>Two 100 mL samples of the solvent were saturated with carbon dioxide by passing pure cylinder CO₂ through the solutions for 30 minutes. One sample was used to determine total CO₂. It was treated with ammonia and barium chloride to precipitate the total CO₂ as barium carbonate which was recovered and treated with acid to liberate the CO₂. The other sample was stripped of unfixed CO₂ by heating strongly under reduced pressure until the solution volume was reduced in half. The fixed CO₂ remaining was treated with ammonia and barium chloride and the barium carbonate recovered and treated with acid to recover the CO₂. The Unfixed CO₂ = Total CO₂ - Fixed CO₂.</p> <p>Compiler's note: The 30 minute saturation time seems too short to attain saturation.</p>	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Described as pure cylinder gas, source not given. (2) Diammonium citrate. Nothing specified. (3) Water. Nothing specified.																										
ESTIMATED ERROR: Temperature: Nothing specified. Solubility: Nothing specified.

<p>AUXILIARY INFORMATION</p>																	
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The apparatus and method are described in earlier papers (1, 2). Solubility is determined in a thermostated, magnetic stirred cylindrical brass bomb with an observation window. The solution is prepared and put in a glass liner in the bomb. The system is sealed, evacuated to a pressure just above water vapor pressure, and out-gassed with stirring for several hours. The gas is added to a known pressure and equilibrated with stirring for a minimum of five hours. Stirring is stopped, the solution is allowed to become still. The gas is vented leaving the supersaturated solution under a gaseous pressure of atmospheric pressure for a fixed time of 30 to 60 seconds. The rate of gas loss during the still condition is measured to use in a later correction. The gas is stirred and collected. The total volume of gas is measured along with ambient pressure and temperature.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Carbon dioxide. Matheson Gas Products. Commercial grade, stated to be 99.5 % min purity.</p> <p>(2) Cetyltrimethylammonium bromide. Lancaster Synthesis Ltd. Stated to be 98.0 %.</p> <p>(3) Water. Nothing specified, but have used doubly distilled water in earlier work.</p> <p>ESTIMATED ERROR:</p> <p>$\delta T/K$ not specified.</p> <p>$\delta m_1/\text{mol kg}^{-1} = 0.02 \times 10^{-2}$</p> <p>REFERENCES:</p> <p>1. AUXILIARY INFORMATION																													
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.																												
ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal.

<p>^a Calculated by the compiler.</p> <p>^b c_2 means the concentration of entities $1/3 \text{ Fe(OH)}_3$. $c_2 = c\{1/3 \text{ Fe(OH)}_3\}$ $M\{1/3 \text{ Fe(OH)}_3\} = 35.621 \text{ g mol}^{-1}$</p> <p>Author: "Although it is uncertain whether the colloids in question have definite chemical formulae, yet for the sake of clearness the gram-equivalent of ferric hydroxide was taken as $1/3 \text{ Fe(OH)}_3 = 35.621$."</p> <p>^c L = Ostwald coefficient (cm^3/cm^3). The values represented in table are mean values of measurements.</p>							
AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE: The method of Ostwald was employed. ¹ The solutions were freed from air by boiling in a vacuum and, without contact with air, transferred to the vacuum mixing vessel at 25 °C. The gas was saturated with water vapor at the same temperature. Five measurements were made with a given solution at five different temperatures, the process being repeated after an interval of several hours to check the former result.				SOURCE AND PURITY OF MATERIALS: (1) Carefully washed. Purity of CO ₂ was confirmed by the value obtained for its solubility in distilled water. (2) A solution of pure ferric hydroxide in acetic acid was diluted and boiled until the ratio of acetic acid to ferric hydroxide became 1:30 - 1:60. The solution was then evaporated under reduced pressure. (3) Not specified.

AUXILIARY INFORMATION																																																																																																																													
METHOD/APPARATUS/PROCEDURE: Either pure CO ₂ gas or CO ₂ -N ₂ mixtures were used in the experiments to maintain a constant $P(CO_2)$. The CO ₂ -N ₂ mixtures were made by pumping predetermined amounts of CO ₂ and N ₂ into a gas tank and their composition was verified by gas chromatography. CO ₂ or CO ₂ -N ₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min ⁻¹ . The mole fraction of CO ₂ in the CO ₂ -N ₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph.	SOURCE AND PURITY OF MATERIALS: (1) Commercial; purity 99.9 %. (2) Source not mentioned. Analytical reagent-grade which met ACS specifications. MgCl ₂ ·6H ₂ O was weighed and dissolved in water. The concentration of MgCl ₂ in solutions was determined by analyzing Cl ⁻ concentration via AgNO ₃ titration in stock solutions. (3) 18 MΩ water obtained from a Milli-Q Super-Q water system. ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta m_1/m_1 = \pm 0.012$ $\delta \gamma_1/\gamma_1 = \pm 0.04$

AUXILIARY INFORMATION																																	
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.																																
ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref. 1.		(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).		
		(2) DDR pro analysis grade by DDR Standard TGL 5021.		
		(3) Double distilled.		
		ESTIMATED ERROR:		
		Not given.

METHOD/APPARATUS/PROCEDURE: Either pure CO ₂ gas or CO ₂ -N ₂ mixtures were used in the experiments to maintain a constant $P(\text{CO}_2)$. The CO ₂ -N ₂ mixtures were made by pumping pre-determined amounts of CO ₂ and N ₂ into a gas tank and their composition was verified by gas chromatography. CO ₂ or CO ₂ -N ₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min ⁻¹ . The mole fraction of CO ₂ in the CO ₂ -N ₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph.	SOURCE AND PURITY OF MATERIALS: (1) Commercial; purity 99.9 %. (2) Source not mentioned. Analytical reagent-grade which met ACS specifications. Vacuum-dried before use. (3) 18 MΩ water obtained from a Milli-Q Super-Q water system. ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta m_1/m_1 = \pm 0.012$ $\delta \gamma_1/\gamma_1 = \pm 0.04$ REFERENCES:

40	-0.0211	0.230		
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The principle of the Ostwald method was used in which the gas is agitated with a measured quantity of gas-free liquid and the decrease in volume of solution-saturated gas is measured in a burette over mercury. The pressure was adjusted to yield one atmosphere partial pressure of carbon dioxide. The volume of gas was reduced to 0°C by the ideal gas law. Experiments were conducted to show that the agitation did not cause super-saturation.		SOURCE AND PURITY OF MATERIALS: (1) Commercial cylinder, 99.8 % pure. (2) Analytical grade. (3) Distilled and degassed.		
		ESTIMATED ERROR: $\delta T/K = <\pm 0.1$ at 0.2°C, ± 0.03 at other temperatures (authors), $\delta\alpha/\alpha, \delta S/S = \pm 0.002$ (authors).

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.			SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.		
			ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal.

AUXILIARY INFORMATION																																																				
METHOD/APPARATUS/PROCEDURE: Salt solution and gas were charged to a 300-ml copper-lined vessel supported in a heater, and were equilibrated by rocking. Temperature was measured by a copper constantan thermocouple placed in a well in the vessel; pressure was measured by a Crosby deadweight balance. Samples were with drawn from the bottom of the vessel into a glass trap; the gas evolved from the sample was measured in a water-jacketed buret over mercury at atmospheric pressure, and the solution residue was weighed. Correction was made for the volume of gas still dissolved in the solution. The total volume was reduced to STP and the number of moles was obtained from the molar volume of carbon dioxide, taken as 22,264 cm ³ . Measurements on a charge of solution were made first at the maximum pressure, after which the pressure was reduced by venting gas. Equilibration and sampling was repeated for measurements at lower pressures.	SOURCE AND PURITY OF MATERIALS: (1) Ohio Chemical Co., medicinal. (2) Baker, cp. (3) No details. AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: Either pure CO ₂ gas or CO ₂ -N ₂ mixtures were used in the experiments to maintain a constant $P(CO_2)$. The CO ₂ -N ₂ mixtures were made by pumping pre-determined amounts of CO ₂ and N ₂ into a gas tank and their composition was verified by gas chromatography. CO ₂ or CO ₂ -N ₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min ⁻¹ . The mole fraction of CO ₂ in the CO ₂ -N ₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph.			SOURCE AND PURITY OF MATERIALS: (1) Commercial; purity 99.9 %. (2) Source not mentioned. Analytical reagent-grade which met ACS specifications. CaCl ₂ ·2H ₂ O was weighed and dissolved in water. The concentration of CaCl ₂ in solutions was determined by analyzing Cl ⁻ concentration via AgNO ₃ titration in stock solutions. (3) 18 MΩ water obtained from a Milli-Q Super-Q water system.

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
<p>Full descriptions of the apparatus and the mode of operation are given elsewhere (Ref. 1). The principle of the method is that a known volume of gas in liquid-saturated vapor state is brought into contact with a measured amount of gas-free liquid. Equilibrium is established by agitation, and the volume of gas remaining is measured. After correction for the solvent vapor pressure, the change in the gas volume gives the solubility. The vapor pressures of the salt solutions at 20 °C were calculated by use of Raoult's law.</p> <p>The gas free solution was prepared by mixing methanol, water and calcium chloride, each of which was separately degassed or desorbed.</p> <p>The compiler calculated the calcium chloride molar concentrations from the ionic strength given in the paper. The methanol mole fraction refers to the salt free liquid. The salt effect in water is in Ref. 1.</p>			(1) Source not given, commercial cylinder. Purity of > 99.8 % confirmed by gas chromatography. (2,3) From Nakarai Chemicals Ltd. (Tokyo). Used without further purification. (4) Distilled.		
			ESTIMATED ERROR:		
			$\delta\alpha/\alpha = \pm 0.01$ (compiler) Mole fraction of salt free solvent reproducible to 0.001.

AUXILIARY INFORMATION																			
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled. ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal. REFERENCES: 1. Setchenow, J. <i>Akad. Nauk. SSSR Mem. Acad. imp. Sci. St. Petersburg</i> <u>1887</u> , 35, [Ser. No. 7], 1-59.

^a Calculated from ionic strength and ratios of ionic strengths given in paper. ^b Quoted in original paper. $I = \text{ionic strength}; \alpha = \text{Bunsen coefficient } [\text{cm}^3 \text{ (STP) cm}^{-3} \text{ atm}^{-1}]$ $P = 1 \text{ atm} = 1.01325 \times 10^5 \text{ Pa}$				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: Concentrated solution prepared by weighting, less concentrated solutions prepared by dilution. Equilibrium established between a measure volume of gas and a measured amount of gas-free liquid in a cell fitted with a magnetic stirrer. Amount of gas absorbed estimated from change in volume of gas. Details in source and ref. (1).		SOURCE AND PURITY OF MATERIALS: (1) Commercial sample, purity 99.8 mole %. (2) Analytical grade sample. (4) No details given.		
		ESTIMATED ERROR: $\delta T/K = \pm 0.2; \delta \alpha = \pm 2 \%$ (estimated by compiler).

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE:			SOURCE AND PURITY OF MATERIALS:		
<p>Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.</p>			<p>(1) Apparently generated from limestone and sulfuric acid. Dried.</p> <p>(2) Not specified.</p> <p>(3) Not specified, assumed to be distilled.</p>

<p>AUXILIARY INFORMATION</p>																																																																										
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref. 1.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).</p> <p>(2) DDR pro analysis grade by DDR Standard TGL 5021.</p> <p>(3) Double distilled.</p> <p>ESTIMATED ERROR:</p> <p>Not given.</p> <p>REFERENCES:</p> <p>1. AUXILIARY INFORMATION																																																																																																			
METHOD/APPARATUS/PROCEDURE: <p>Full descriptions of the apparatus and the mode of operation are given elsewhere (Ref. 1). The principle of the method is that a known volume of gas in liquid-saturated vapor state is brought into contact with a measured amount of gas-free liquid. Equilibrium is established by agitation, and the volume of gas remaining is measured. After correction for the solvent vapor pressure, the change in the gas volume gives the solubility. The vapor pressures of the salt solutions at 20 °C were calculated by use of Raoult's law.</p> <p>The gas free solution was prepared by mixing methanol, water and lithium chloride, each of which was separately degassed or desorbed.</p> <p>In the paper the lithium chloride concentration was labelled ionic strength. The methanol mole fraction refers to the salt free liquid.</p>	SOURCE AND PURITY OF MATERIALS: (1) Source not given, commercial cylinder. Purity of > 99.8 % confirmed by gas chromatography. (2,3) From Nakarai Chemicals Ltd. (Tokyo). Used without further purification. (4) Distilled.																																																																																																		
	ESTIMATED ERROR: $\delta\alpha/\alpha = \pm 0.01$ (compiler) Mole fraction of salt free solvent reproducible to 0.001.

<hr/> ^a Calculated by the compiler. ^b S_1 = solubility coefficient of CO ₂ . $S_1 = (V'_1 - V)/v$, where $(V'_1 - V)$ is the volume of CO ₂ dissolved at pressure P , and v is the volume of the aqueous Li ₂ SO ₄ solution. The paper contained no definitive information about the pressure P . The measurements probably were made at atmospheric pressure. ^c k = Sechenov constant, defined by equation $\lg(S_0/S_1) = kc_2$, where S_0 and S_1 are the solubility coefficients of CO ₂ in pure water and in Li ₂ SO ₄ solution, respectively, and c_2 is the concentration of Li ₂ SO ₄ in the aqueous Li ₂ SO ₄ solution.				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: A volume V_1 of carbon dioxide, saturated with water vapor, was introduced into Bunte's burette under atmospheric pressure and at the temperature of 17 °C. A volume v of aqueous Li ₂ SO ₄ solution of known concentration was then introduced, and the mixture was stirred until no diminution of volume was observed. When the initial temperature was reached, the volume V was read under the pressure P . The volume V_1 at the partial pressure P_1 of CO ₂ was reduced to volume V'_1 at pressure P ; $(V'_1 = V_1P_1/P)$. The solubility coefficient S_1 of CO ₂ was calculated from the equation $S_1 = \frac{(V'_1 - V)}{v}$		SOURCE AND PURITY OF MATERIALS: Nothing specified.		
		ESTIMATED ERROR: Nothing specified.

<p>AUXILIARY INFORMATION</p>																																																																																						
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref.1.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).</p> <p>(2) DDR pro analysis grade by DDR Standard TGL 5021.</p> <p>(3) Double distilled.</p> <p>ESTIMATED ERROR:</p> <p>Not given.</p> <p>REFERENCES:</p> <p>1. AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.			SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.		
			ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal.

AUXILIARY INFORMATION																																																																																																											
METHOD/APPARATUS/PROCEDURE: <p>The same apparatus and method were used for measurements of solubility and electromotive force. A detailed description of the experimental procedure is available in the source.</p> <p>Equilibrium in the cell was attained by bubbling CO₂ through the solvent while gently rocking the thermostatted cell. Pressure was maintained constant at 1 atm. The concentration was determined by titrating about 90 cm³ of solution with excess standard Ba(OH)₂ solution and back-titrating the excess.</p>	SOURCE AND PURITY OF MATERIALS: (1) From commercial tank. Purity 99.67 % ± 0.05 %. (2) 99.98 % pure (2) Quality not stated. Degassed by CO ₂ bubbling and evacuation. ESTIMATED ERROR: $\delta S_1 = \pm (0.2-0.5) \%$, while at high temperatures and salt concentrations $\delta S_1 = \pm 1 \%$. ^a Calculated by the compiler.

^b m_2 = molality of NaCl.

^c $S_1 = m_1/P_1$ where m_1 is the molality of CO₂ [mol kg⁻¹].

The S_1 values are at $P_1 = 1$ atm.

The starred values were not given as great a weight as the unstarred values in the final graphical estimation of S_1 .

^d **Series A** represents the mean of four simultaneous measurements of CO₂ in water. In addition, this series comprises single observations of the solubility in 0.2, 0.5, 1, 2, and 3 mol kg⁻¹ NaCl solutions.

Series B represents the mean of three experiments at each temperature on each salt concentration recorded.

Series C: the results of series A and B were plotted on a large scale and all results in doubt redetermined.

The authors made large scale plots of $(-\lg S_1)$ versus molality of NaCl. The smoothed values obtained from these graphs are given in Table 2.

Table 2. Smoothed values of $(-\lg S_1)$. Deviations (Obs. - Calcd.)^e

^e Numbers in parentheses represent deviations in fourth decimal place of $(-\lg S_1)$.

(continued next page)

COMPONENTS:	ORIGINAL MEASUREMENTS:
(1) Carbon dioxide; CO ₂ ; [124-38-9]	Harned, H.S.; Davis, R. Jr.
(2) Sodium chloride; NaCl; [7647-14-5]	<i>J. Am. Chem. Soc.</i> <u>1943</u> , 65, 2030-7.
(3) Water; H ₂ O; [7732-18-5]	

EXPERIMENTAL VALUES: (continued)

The authors expressed the solubility data as a function of the absolute temperature by equation (1):

$$- \lg S_1 = -A^*/T + D^* - C^*T \quad (1)$$

The parameters of equation (1), obtained from the data by method of least squares, are given in Table 3.

Table 3. Least squared constants of equation (1).

$m_2/\text{mol kg}^{-1} \text{ }^b$	A^*/K	D^*	C^*/K^{-1}
0.0	2385.73	14.0184	0.0152642
0.2	2347.16	13.8090	0.0149259
0.5	2309.60	13.6316	0.0146492
1.0	2195.84	12.9875	0.0136050
2.0	1912.43	11.2968	0.0108268
3.0	1622.96	9.5253	0.0078770

^b m_2 = molality of NaCl.

The deviations of the observed results from those calculated by equation (1) are given in parentheses immediately following the values in Table 2 (previous page). The maximum deviation is 0.0036 and the average deviation is 0.0015 in $\lg S_1$ which corresponds to 0.8 and 0.3 % in S_1 .

AUXILIARY INFORMATION																					
METHOD/APPARATUS/PROCEDURE: <p>The prepared solvent and solution were charged into an evacuated cell after degassing, and the mass of solvent was determined by weight. Gas was introduced into the cell from a measuring buret in which the gas was stored over mercury. The cell was agitated while the gas pressure was maintained by adjusting the gas volume. The Ostwald coefficient was determined from the mass of solvent and the volume of gas absorbed. Solubilities were measured at pressures above and below atmospheric.</p>	SOURCE AND PURITY OF MATERIALS: <ol style="list-style-type: none"> (1) Source and purity not given. An aqueous "soda" solution absorbed 99.8 % of the gas. (2) Source and purity not given. Recrystallized from water and dried. (3) Boiled to remove carbon dioxide. ESTIMATED ERROR: $\delta T/K = \pm 0.2$ $\delta p/\text{kPa} = \pm 0.1$ $\delta L/L = \pm 0.02 \text{ (compiler)}$ REFERENCES: Some data in the thesis have been published. AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The experimental apparatus was the same used in previous experimental work. ¹ After equilibration the CO ₂ and NaCl content of the liquid samples was analyzed. The CO ₂ composition was determined by titration against standard HCl solution. CO ₂ was absorbed in sodium hydroxide and estimated by back titration with HCl. The NaCl concentration of the solution was determined by the Mohr method using standardized AgNO ₃ solution and a potassium chromate solution as an indicator. The composition of the co-existing gas phase was not determined.			SOURCE AND PURITY OF MATERIALS: (1), (2), and (3): Source and purity not stated.

<p>AUXILIARY INFORMATION</p>																																																																										
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref.1.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).</p> <p>(2) DDR pro analysis grade by DDR Standard TGL 5021.</p> <p>(3) Double distilled.</p> <p>ESTIMATED ERROR:</p> <p>Not given.</p> <p>REFERENCES:</p> <p>1. Gerecke, J.; Bittrich, H.J. <i>Wiss. Z. Tech. Hochsch. Chem. "Carl Schorlemmer" Leuna-Merseburg</i> <u>1971</u>, 13(2), 115-22.</p>

^a Calculated by the compiler.					
^b $K_H = P_1\phi_1/x_1$, where K_H = Henry's law constant, P_1 = partial pressure of gas ($P_1 = P - P_2$; P_2 is the vapor pressure of water at the corresponding temperature), ϕ_1 = fugacity coefficient (Smith, J.M. and Van Ness, H.C. <i>Chemical Engineering Thermodynamics</i> , McGraw-Hill, New York 1959), and x_1 = mole fraction of the dissolved CO ₂ .					
AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The solubility of CO ₂ was determined from pressure-volume-temperature (PVT) measurements using the technique of gas extraction. The apparatus consisted of (1) a high-pressure, high-temperature section for dissolving the gas in the brine, (2) a heat exchanger for cooling (or heating) samples of gas-saturated brine to room temperature, and (3) a low-pressure, constant temperature section for making PVT measurements on collected gas and liquid samples. A two liter, type 316 stainless steel stirred reactor, fitted with a heat- and chemical-resistant glass liner, was filled two-thirds full with brine. The brine was deaerated by evacuating the reactor to the vapor pressure of the brine for at least 3 minutes. Upon reaching thermal equilibrium, the gas was injected into the reactor and allowed to distribute at a fixed partial pressure between the vapor and liquid phases. Equilibration occurred within 5 hours at 150 °C and above, and within 24 hours at lower temperatures. The concentration of CO ₂ in the liquid was determined by desorption from a known volume of liquid followed by volumetric analysis of the evolved gas.			SOURCE AND PURITY OF MATERIALS: (1) 99.5 %. (2) Reagent grade. (3) Demineralized.		
			ESTIMATED ERROR: $\delta K_H/K_H = 0.058$ (by author) (Detailed analysis of experimental contributions to the total error is given in the source.)

AUXILIARY INFORMATION																																																																																																																															
METHOD/APPARATUS/PROCEDURE: <p>Schematic diagrams of the apparatus, equilibrium cell, and sample analysis apparatus are shown in the source.</p> <p>Approximately 500 mL of liquid was injected into the equilibrium cell. The cell was sealed and heated to the test temperature. Once thermal equilibrium was achieved, approximately 500 mL of CO₂ at 6 MPa was added from the CO₂ cylinder. The system pressure was increased to about 11 MPa by inserting the cell piston. The equilibrium cell was agitated until equilibrium at 10 MPa was achieved. Equilibrium was assumed when no cell pressure variation was observed over a 12 h period. Once equilibrium was reached, agitation was stopped and a sample of the liquid phase was withdrawn for analysis. The above procedure was then repeated decreasing the pressure by 2 MPa steps until the last samples at 2 MPa were collected.</p>	SOURCE AND PURITY OF MATERIALS: (1) Coleman Instrument grade with a minimum purity 99.99 %. (2) Fisher Scientific laboratory grade with 99.98 % purity. (3) Purified using a reverse osmosis system to a minimum resistance of 17 MΩ. ESTIMATED ERROR: $\delta T/T \leq \pm 0.005$; $\delta P/P \leq \pm 0.017$ $\delta x_1/x_1 = 0.02$; $\delta \rho/\text{kg m}^{-3} = 3$ REFERENCES:

AUXILIARY INFORMATION																																																																																																	
METHOD/APPARATUS/PROCEDURE: Either pure CO ₂ gas or CO ₂ -N ₂ mixtures were used in the experiments to maintain a constant $P(CO_2)$. The CO ₂ -N ₂ mixtures were made by pumping predetermined amounts of CO ₂ and N ₂ into a gas tank and their composition was verified by gas chromatography. CO ₂ or CO ₂ -N ₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min ⁻¹ . The mole fraction of CO ₂ in the CO ₂ -N ₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph.	SOURCE AND PURITY OF MATERIALS: (1) Commercial; purity 99.9 %. (2) Source not mentioned. Analytical reagent-grade which met ACS specifications. Vacuum-dried before use. (3) 18 MΩ water obtained from a Milli-Q Super-Q water system. ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta m_1/m_1 = \pm 0.012$ $\delta \gamma_1/\gamma_1 = \pm 0.04$ REFERENCES:

AUXILIARY INFORMATION																																																																																																					
METHOD/APPARATUS/PROCEDURE: <p>The apparatus is a modification of one used in earlier work (1). It consists of a 30 mL high pressure optical cell, thermostat, magnetic stirrer, thermocouples and Pt resistance thermometer, pressure transducers and tanks for aqueous solutions, rinse water and solute gas. Measured amounts of gas and solvent are added to the cell, extra solvent is added until the gas phase disappears. The pressure is reduced by removing stepwise small known amounts of solvent until a small stable bubble appears. The solubility is calculated from the known amounts of solvent and carbon dioxide in the cell.</p>	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Messer Griesheim, Ludwigshafen, > 99.995 mol %, used as received. (2) Sodium chloride. Merck GmbH, Darmstadt. > 99.9 mass %. Degassed and dried under vacuum. (3) Water. Deionized and degassed by vacuum distillation. ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta p/p < \pm 0.03$ below 6 MPa $\delta p/p < \pm 0.05$ at higher pressures $\delta m_2/m_2 = \pm 0.003$ $\delta m_1/m_1 = \pm 0.01$ to 0.03

AUXILIARY INFORMATION																																													
METHOD/APPARATUS/PROCEDURE: <p data-bbox="144 1324 686 1651"> The apparatus is a combination of previous designs (Refs 1 and 2). It was modified to achieve a more accurate determination of the volume of the absorbed liquid. The apparatus measures the volume of absorbed gas as the volume of mercury that must be supplied to the system in order to restore the initial pressure. The raw solubility data obtained are gas/liquid volume ratios. A detailed description of apparatus, method and procedure is given in Ref. 3. </p>	SOURCE AND PURITY OF MATERIALS: (1) Commercial, purity 99.5 mole %. (2) No details given. (3) Distilled and degassed.

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The apparatus is a combination of previous designs (Refs 1 and 2). It was modified to achieve a more accurate determination of the volume of the absorbent liquid. The apparatus measures the volume of absorbed gas as the volume of mercury that must be supplied to the system in order to restore the initial pressure. The raw solubility data obtained are gas/liquid volume ratios. A detailed description of apparatus, method and procedure is given in Ref. 3.			SOURCE AND PURITY OF MATERIALS: (1) Commercial, purity 99.95 mole %. (2) Probus. Grade not given. (3) Distilled and degassed.		
			ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta P/\text{bar} = \pm 0.001$ $\delta c_1/c_1 < \pm 1\%$ (estimated by compiler on the basis of the information in Ref. 3)

AUXILIARY INFORMATION																																																	
METHOD/APPARATUS/PROCEDURE: Two procedures were used for saturating solutions with CO ₂ : <u>Saturation by bubbling (B).</u> The solution was placed in the saturating tube, the lower end of which was connected through a wash bottle with a Kipp CO ₂ generator. The tube and wash bottle were immersed in a constant temperature bath. CO ₂ gas was bubbled through it rapidly for 30 minutes. The wash bottle was replaced by a mercury reservoir and the free gas was driven completely out of the saturating tube by admitting mercury underneath the solution. The CO ₂ contents of the solutions were determined in the manometric gas apparatus (Refs 1 and 2). <u>Saturation in rotating tonometer (T).</u> The technique used was that described by Austin et al. (Ref. 3). Both procedures gave identical results with solutions of acids and salts.	SOURCE AND PURITY OF MATERIALS: (1) From a Kipp CO ₂ generator. (2) Not specified. (3) Not specified. (4) Distilled.

^a Calculated from ionic strength and ratios of ionic strengths given in paper. ^b Quoted in original paper. $I =$ ionic strength; $\alpha =$ Bunsen coefficient [cm ³ (STP) cm ⁻³ atm ⁻¹] $P = 1\ atm = 1.01325 \times 10^5\ Pa$				
AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: Concentrated solution prepared by weighting, less concentrated solutions prepared by dilution. Equilibrium established between a measure volume of gas and a measured amount of gas-free liquid in a cell fitted with a magnetic stirrer. Amount of gas absorbed estimated from change in volume of gas. Details in source and ref. (1).		SOURCE AND PURITY OF MATERIALS: (1) Commercial sample, purity 99.8 mole %. (2) Analytical grade sample. (4) No details given.		
		ESTIMATED ERROR: $\delta T/K = \pm 0.2$; $\delta \alpha = \pm 2\ %$ (estimated by compiler).

AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
Volumetric apparatus with multibulb buret and magnetic stirrer. Amount of solution and gas absorbed determined volumetrically. Partial pressure determined from total pressure and vapor pressure of solution. The vapor pressure of the mixed salt solution estimated by the method of Robinson and Bower (1) from corresponding data for each component salt solution. Apparatus similar to that described in ref. (2).		(1) Extra pure grade, purity 99.96 mole %. (2,3) Reagent grade. (4) Deionized.	
		ESTIMATED ERROR: $\delta T/K = \pm 0.05$; $\delta L = \pm 1 \%$.

<p>AUXILIARY INFORMATION</p>																																																																																					
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Either pure CO₂ gas or CO₂-N₂ mixtures were used in the experiments to maintain a constant $P(\text{CO}_2)$. The CO₂-N₂ mixtures were made by pumping predetermined amounts of CO₂ and N₂ into a gas tank and their composition was verified by gas chromatography. CO₂ or CO₂-N₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min⁻¹. The mole fraction of CO₂ in the CO₂-N₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) Commercial; purity 99.9 %.</p> <p>(2,3) Source not mentioned. Analytical reagent-grade which met ACS specifications. Vacuum-dried before use.</p> <p>(4) 18 MΩ water obtained from a Milli-Q Super-Q water system.</p> <p>ESTIMATED ERROR:</p> <p style="text-align: center;">$\delta T/K = \pm 0.1$</p> <p style="text-align: center;">$\delta m_1/m_1 = \pm 0.012$</p> <p style="text-align: center;">$\delta \gamma_1/\gamma_1 = \pm 0.04$</p> <p>REFERENCES:</p>

AUXILIARY INFORMATION																																																						
METHOD/APPARATUS/PROCEDURE: Static-state method. The authors designed a solubility apparatus which is composed of three isothermal pre-saturators, saturator and sampler. A schematic diagram of the apparatus is in the original source. CO ₂ was introduced (10 hours) through the pre-saturators and the saturator which contained about 120 g of solvent. The equilibrated sample (about 100 g) was transferred from the saturator into the weighed sampler which contained a weighed amount of standard NaOH solution. The sampler was weighed again and shaken to complete the reaction between CO ₂ and NaOH. The excess of NaOH and the NaHCO ₃ was titrated potentiometrically with standard HCl solution. The mass of dissolved CO ₂ was calculated from the equation $w = c_{\text{HCl}}(V_2 - V_1)M$	SOURCE AND PURITY OF MATERIALS: (1) Purity of CO ₂ 99.95 %. (2) Primary-standard grade NaCl was dried in an oven at 170 °C for 3 hours and stored in desiccator. (3) Not specified. (4) Double deionized. Conductivity of H ₂ O was < 1.5×10 ⁻⁴ S m ⁻¹																																																					
where w = mass of dissolved CO ₂ , c_{HCl} = concentration of HCl; V_1 and V_2 are volumes of the HCl solution to the first and second end point, respectively, and M = molar mass of CO ₂ .	ESTIMATED ERROR: $\delta T/K = \pm 0.02$ When fitting the data to the equation $\lg S_1 = A/T + B + CT$, the standard deviation σ was $0.02 < \sigma < 0.4$. (See Table 3 on the net page.)																																																					

COMPONENTS:	ORIGINAL MEASUREMENTS:
(1) Carbon dioxide; CO ₂ ; [124-38-9]	Yuan, C-B.; Yang, J-Z.

(4) Water; H ₂ O; [7732-18-5]	

EXPERIMENTAL VALUES: (continued)

The authors computed Setchenov salt effect parameter k_{smm} . Setchenow salt effect equation was given as

$$\lg (S^{\circ}/S_m) = k_{\text{smm}}m_2 \quad (1)$$

where

S° = solubility of CO₂ in 15 mass-% glucose/water solution without NaCl,
 S_m = solubility of CO₂ in 15 mass-% glucose/water solution with NaCl,
 m_2 = molality of NaCl in 15 mass-% glucose/water solution

k_{smm} was obtained from the slope of the graph $\lg (S^{\circ}/S_m)$ vs. m_2 .
 Values for k_{smm} computed at each temperature are listed in Table 2.

Table 2. Setchenow salt effect parameters for the solubility of CO₂ in
 in NaCl + 15 mass-% glucose/water solution at 278.15 to 318.15 K

T/K	278.15	288.15	298.15	308.15	318.15
$10^2 k_{\text{smm}}/\text{mol kg}^{-1}$	8.48	7.57	6.67	6.11	4.76

The experimental solubilities from Table 1 were fitted to an equation

$$\lg S_1 = A/T + B + CT \quad (2)$$

The coefficients of eq. (2) and the standard deviation in $\lg S_1$ are listed in Table 3.

Table 3. Coefficients of eq. (2) for smoothed results for solubility of
 CO₂ in pure H₂O, 15 mass-% glucose/H₂O and NaCl+15 % glucose/H₂O

System	A	B	C	σ^a
Pure H ₂ O	4608.8	-28.953	0.04018	0.02
15 mass-% glucose/H ₂ O	2754.4	-16.607	0.01940	0.03
1 mol kg ⁻¹ NaCl + 15 % glucose/H ₂ O	4181.1	-26.490	0.03625	0.04
3 mol kg ⁻¹ NaCl + 15 % glucose/H ₂ O	1482.2	- 9.3530	0.008815	0.02

^a σ = standard deviation in $\lg S_1$

Using the values of Table 3, the thermodynamic quantities of the solution process for dissolving CO₂ can be calculated from the following relations:

$$\Delta G^{\circ} = -2.303R(A + BT + CT^2) \quad (3)$$

$$\Delta H^{\circ} = -2.303R(A - CT^2) \quad (4)$$

$$\Delta S^{\circ} = -2.303R(-B - 2CT^2) \quad (5)$$

$$\Delta C_p^{\circ} = -2.303R(- 2CT^2) \quad (6)$$

COMPONENTS: (1) Carbon dioxide; CO ₂ ; [124-38-9] (2) Sodium chlorate; NaClO ₃ ; [7775-09-9] (3) Water; H ₂ O; [7732-18-5]	ORIGINAL MEASUREMENTS: Setchenow, J. [Sechenov, I.M.] <i>Ann. Chim. Phys.</i> [6] <u>1892</u> , 25, 226-70.

AUXILIARY INFORMATION																									
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled. AUXILIARY INFORMATION							
METHOD/APPARATUS/PROCEDURE: The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. The molar concentration of salt in the liquid was standardized at 20 °C. These data are analyzed and discussed further in Ref. 1. AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: The prepared solvent and solution were charged into an evacuated cell after degassing, and the mass of solvent was determined by weight. Gas was introduced into the cell from a measuring buret in which the gas was stored over mercury. The cell was agitated while the gas pressure was maintained by adjusting the gas volume. The Ostwald coefficient was determined from the mass of solvent and the volume of gas absorbed. Solubilities were measured at pressures above and below atmospheric.			SOURCE AND PURITY OF MATERIALS: (1) Source and purity not given. An aqueous "soda" solution absorbed 99.8 % of the gas. (2) Source and purity not given. Recrystallized from water and dried. (3) Boiled to remove carbon dioxide.		
			ESTIMATED ERROR: $\delta T/K = \pm 0.2$; $\delta p/\text{kPa} = \pm 0.1$ $\delta L/L = \pm 0.02$ (compiler)

AUXILIARY INFORMATION																																											
METHOD/APPARATUS/PROCEDURE: <p>The apparatus is a combination of previous designs (Refs 1 and 2). It was modified to achieve a more accurate determination of the volume of the absorbent liquid. The apparatus measures the volume of absorbed gas as the volume of mercury that must be supplied to the system in order to restore the initial pressure. The raw solubility data obtained are gas/liquid volume ratios. A detailed description of apparatus, method and procedure is given in Ref. 3.</p>	SOURCE AND PURITY OF MATERIALS: (1) Commercial, purity 99.95 mole %. (2) Merck. Grade not given. (3) Distilled and degassed.																																										
ESTIMATED ERROR: $\delta T/K = \pm 0.1$ $\delta P/\text{bar} = \pm 0.001$ $\delta c_1/c_1 < \pm 1\%$ (estimated by compiler on the basis of the information in Ref. 3)

AUXILIARY INFORMATION																					
METHOD/APPARATUS/PROCEDURE: The prepared solvent and solution were charged into an evacuated cell after degassing, and the mass of solvent was determined by weight. Gas was introduced into the cell from a measuring buret in which the gas was stored over mercury. The cell was agitated while the gas pressure was maintained by adjusting the gas volume. The Ostwald coefficient was determined from the mass of solvent and the volume of gas absorbed. Solubilities were measured at pressures above and below atmospheric.	SOURCE AND PURITY OF MATERIALS: <ol style="list-style-type: none"> (1) Source and purity not given. An aqueous "soda" solution absorbed 99.8 % of the gas. (2) Source and purity not given. Recrystallized from water and dried. (3) Boiled to remove carbon dioxide. ESTIMATED ERROR: $\delta T/K = \pm 0.2$ $\delta p/\text{kPa} = \pm 0.1$ $\delta L/L = \pm 0.02 \text{ (compiler)}$ REFERENCES: Some data in the thesis have been published. See: 1. AUXILIARY INFORMATION																																																							
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.																																																						
ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The principle of the Ostwald method was used in which the gas is agitated with a measured quantity of gas-free liquid and the decrease in volume of solution-saturated gas is measured in a burette over mercury. The pressure was adjusted to yield one atmosphere partial pressure of carbon dioxide. The volume of gas was reduced to 0°C by the ideal gas law. Experiments were conducted to show that the agitation did not cause super-saturation.		(1) Commercial cylinder, 99.8 % pure.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref.1.		(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).		
		(2) DDR pro analysis grade by DDR Standard TGL 5021.		
		(3) Double distilled.

AUXILIARY INFORMATION																																																			
METHOD/APPARATUS/PROCEDURE: The apparatus was designed for the measurement of Na ₂ SO ₄ solubility in aqueous solutions of CO ₂ . The equilibrium cell is a high pressure stainless steel Jerguson liquid level gage with an internal volume of about 150 mL. Mixing is achieved by recirculating both phases for about 4 hours. The apparatus is in an air bath controlled to ± 0.1 K, pressure is measured with a Heise bourdan tube pressure gage to ± 0.02 MPa. The carbon dioxide is measured in a calibrated, about 1.3 mL, sampling loop. The gas is "flushed" to atm pressure and the volume of CO ₂ gas measured to an accuracy of 1 % by displacement of a CO ₂ saturated aqueous solution. AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: Either pure CO ₂ gas or CO ₂ -N ₂ mixtures were used in the experiments to maintain a constant $P(\text{CO}_2)$. The CO ₂ -N ₂ mixtures were made by pumping predetermined amounts of CO ₂ and N ₂ into a gas tank and their composition was verified by gas chromatography. CO ₂ or CO ₂ -N ₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min ⁻¹ . The mole fraction of CO ₂ in the CO ₂ -N ₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph.			SOURCE AND PURITY OF MATERIALS: (1) Commercial; purity 99.9 %. (2) Source not mentioned. Analytical reagent-grade which met ACS specifications. Vacuum-dried before use. (3) 18 MΩ water obtained from a Milli-Q Super-Q water system.

<p style="text-align: center;">AUXILIARY INFORMATION</p>											
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The apparatus is a modification of one used in earlier work (1). It consists of a high pressure optical cell, thermostat, magnetic stirrer, thermocouples and Pt resistance thermometer, pressure transducers and tanks for aqueous solutions, rinse water and solute gas. The thermostated about 30 mL high pressure optical cell is filled with carbon dioxide. Pressure and temperature of the gas are measured after equilibration. A known amount of aqueous solvent is added which is slightly greater than that needed to completely dissolve the gas. The pressure in the cell is reduced stepwise by removing very small amounts of the liquid until the first stable bubble appears. The mass of carbon dioxide is calculated from the Bender equation (2). The volume of the cell is known within 0.06 mL. The solvent density is from the literature.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <ol style="list-style-type: none"> (1) Carbon dioxide. EXPERIMENTAL VALUES: <p>The authors estimated the solubility of carbon dioxide in the multicomponent electrolyte system from the results of the carbon dioxide solubility in the single electrolyte aqueous solutions. The authors approach and approximation used are outlined in the paper.</p> <p style="text-align: center;">(continued on the next page)</p>	
AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: <p>The apparatus is a modification of one used in earlier work (1). It consists of a high pressure optical cell, thermostat, magnetic stirrer, thermocouples and Pt resistance thermometer, pressure transducers and tanks for aqueous solutions, rinse water and solute gas.</p> <p>The thermostated about 30 mL high pressure optical cell is filled with carbon dioxide. Pressure and temperature of the gas are measured after equilibration. A known amount of aqueous solvent is added which is slightly greater than that needed to completely dissolve the gas. The pressure in the cell is reduced stepwise by removing very small amounts of the liquid until the first stable bubble appears.</p> <p>The mass of carbon dioxide is calculated from the Bender equation (2). The volume of the cell is known within 0.06 mL. The solvent density is from the literature.</p>	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: Volumetric apparatus with multibulb buret and magnetic stirrer. Amount of solution and gas absorbed determined volumetrically. Partial pressure determined from total pressure and vapor pressure of solution. The vapor pressure of the mixed salt solution estimated by the method of Robinson and Bower (1) from corresponding data for each component salt solution. Apparatus similar to that described in ref. (2).			SOURCE AND PURITY OF MATERIALS: (1) Extra pure grade, purity 99.96 mole %. (2,3,4) Reagent grade. (5) Deionized.		
			ESTIMATED ERROR: $\delta T/K = \pm 0.05$; $\delta L = \pm 1 \%$.

AUXILIARY INFORMATION																																																	
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled. ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal. REFERENCES: 1. Setchenow, J. <i>Akad. Nauk. SSSR Mem. Acad. imp. Sci. St. Petersburg</i> <u>1887</u> , 35, [Ser. No. 7], 1-59.

AUXILIARY INFORMATION

METHOD/APPARATUS/PROCEDURE:

The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref.1.

SOURCE AND PURITY OF MATERIALS:

- (1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).
- (2) DDR pro analysis grade by DDR Standard TGL 5021.
- (3) Double distilled.

ESTIMATED ERROR:

Not given.

<p>AUXILIARY INFORMATION</p>																																																														
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Solutions were saturated with CO₂ by a bubbling method:</p> <p><u>Saturation by bubbling.</u> The solution was placed in the saturating tube, the lower end of which was connected through a wash bottle with a Kipp CO₂ generator. The tube and wash bottle were immersed in a constant temperature bath. CO₂ was bubbled through it rapidly for 30 minutes. The wash bottle was replaced by a mercury reservoir and the free gas was driven completely out of the saturating tube by admitting mercury underneath the solution. The CO₂ contents of the solutions were determined in the manometric gas apparatus (Refs 1 and 2).</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) From a Kipp CO₂ generator.</p> <p>(2) The NaH₂PO₄ solutions were prepared by addition of NaOH to standard H₃PO₃.</p> <p>(3) Not specified.</p> <p>(4) Distilled.</p> <p>ESTIMATED ERROR:</p> <p>$\delta T/K = \pm 0.1$</p> <p>$\delta \alpha/\alpha = \pm 0.005$</p> <p>REFERENCES:</p> <p>1. AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
<p>The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref.1.</p>		(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).		
		(2) DDR pro analysis grade by DDR Standard TGL 5021.		
		(3) Double distilled.		
		ESTIMATED ERROR:		
		Not given.

AUXILIARY INFORMATION								
METHOD/APPARATUS/PROCEDURE: The absorption vessel was 500 mL five-necked glass flask, to which a fixed amount (ca. 400 ml) of sodium phenoxide solution was placed. Carbon dioxide and air, both washed and dried, were mixed together and brought into contact with sodium phenoxide solution without stirring at atmospheric total pressure. Equilibrium was confirmed by the gas volume in the gas burette and chemical analysis of the solution.				SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. From a cylinder, purity not specified. (2) Sodium phenoxide. Sodium hydroxide was dissolved in distilled water, impurities filtered out, diluted with distilled water, and equivalent amount of phenol was dissolved. (3) Water. Distilled.				
				ESTIMATED ERROR: Nothing specified.				

^a Calculated by the compiler.

^b Solubility of CO₂ (mol/dm³ sln).

^c $(c_1/p_1)/mol\ dm^{-3}\ atm^{-1}$ = solubility of CO₂ at its one atm partial pressure.

<p>AUXILIARY INFORMATION</p>																																																							
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>Two procedures were used for saturating solutions with CO₂:</p> <p><u>Saturation by bubbling (B).</u> The solution was placed in the saturating tube, the lower end of which was connected through a wash bottle with a Kipp CO₂ generator. The tube and wash bottle were immersed in a constant temperature bath. CO₂ gas was bubbled through it rapidly for 30 minutes. The wash bottle was replaced by a mercury reservoir and the free gas was driven completely out of the saturating tube by admitting mercury underneath the solution. The CO₂ contents of the solutions were determined in the manometric gas apparatus (Refs 1 and 2).</p> <p><u>Saturation in rotating tonometer (T).</u> The technique used was that described by Austin et al. (Ref. 3).</p> <p>Both procedures gave identical results with solutions of acids and salts.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) From a Kipp CO₂ generator.</p> <p>(2) Na-lactate solutions were made by adding known excess of lactic acid to solutions of NaHCO₃.</p> <p>(3) Not specified.</p> <p>(4) Distilled.</p> <p>ESTIMATED ERROR:</p> <p>$\delta T/K = \pm 0.1$</p> <p>$\delta\alpha/\alpha = \pm 0.005$</p> <p>REFERENCES:</p> <p>1. AUXILIARY INFORMATION																		
METHOD/APPARATUS/PROCEDURE: <p>The apparatus and method are described in earlier papers (1, 2). Solubility is determined in a thermostated, magnetic stirred cylindrical brass bomb with an observation window. The solution is prepared and put in a glass liner in the bomb. The system is sealed, evacuated to a pressure just above water vapor pressure, and outgassed with stirring for several hours. The gas is added to a known pressure and equilibrated with stirring for a minimum of five hours. Stirring is stopped, the solution is allowed to become still. The gas is vented leaving the supersaturated solution under a gaseous pressure of atmospheric pressure for a fixed time of 30 to 60 seconds. The rate of gas loss during the still condition is measured to use in a later correction. The gas is stirred and collected. The total volume of gas is measured along with ambient pressure and temperature.</p>	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Matheson Gas Products. Commercial grade, stated to be 99.5 % min purity. (2) Sodium dodecyl sulfate. BDH Prod. No. 44244, Lot No. 908811C, stated to be 99.0 %. (3) Water. Nothing specified, but have used doubly distilled water in earlier work.																	
ESTIMATED ERROR: $\delta T/K$ not specified. $\delta m_1/\text{mol kg}^{-1} = 0.02 \times 10^{-2}$

AUXILIARY INFORMATION																					
METHOD/APPARATUS/PROCEDURE: The apparatus and method are described in earlier papers (1, 2). Solubility is determined in a thermostated, magnetic stirred cylindrical brass bomb with an observation window. The solution is prepared and put in a glass liner in the bomb. The system is sealed, evacuated to a pressure just above water vapor pressure, and outgassed with stirring for several hours. The gas is added to a known pressure and equilibrated with stirring for a minimum of five hours. Stirring is stopped, the solution is allowed to become still. The gas is vented leaving the supersaturated solution under a gaseous pressure of atmospheric pressure for a fixed time of 30 to 60 seconds. The rate of gas loss during the still condition is measured to use in a later correction. The gas is stirred and collected. The total volume of gas is measured along with ambient pressure and temperature.	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Matheson Gas Products. Commercial grade, stated to be 99.5 % min purity. (2) Sodium perfluorooctanoate. Prepared <i>in situ</i> by titrating perfluorooctanoic acid with sodium hydroxide to pH 9-12. (3) Water. Nothing specified, but have used doubly distilled water in earlier work. ESTIMATED ERROR: $\delta T/K$ not specified. $\delta m_1/\text{mol kg}^{-1} = 0.02 \times 10^{-2}$ REFERENCES: 1. AUXILIARY INFORMATION																															
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.	SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.																														
ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The principle of the Ostwald method was used in which the gas is agitated with a measured quantity of gas-free liquid and the decrease in volume of solution-saturated gas is measured in a burette over mercury. The pressure was adjusted to yield one atmosphere partial pressure of carbon dioxide. The volume of gas was reduced to 0°C by the ideal gas law. Experiments were conducted to show that the agitation did not cause super-saturation.		SOURCE AND PURITY OF MATERIALS: (1) Commercial cylinder, 99.8 % pure. (2) Analytical grade. (3) Distilled and degassed.

METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref. 1.		(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).		
		(2) DDR pro analysis grade by DDR Standard TGL 5021.

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: Either pure CO ₂ gas or CO ₂ -N ₂ mixtures were used in the experiments to maintain a constant $P(\text{CO}_2)$. The CO ₂ -N ₂ mixtures were made by pumping predetermined amounts of CO ₂ and N ₂ into a gas tank and their composition was verified by gas chromatography. CO ₂ or CO ₂ -N ₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min ⁻¹ . The mole fraction of CO ₂ in the CO ₂ -N ₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph.			SOURCE AND PURITY OF MATERIALS: (1) Commercial; purity 99.9 %. (2) Source not mentioned. Analytical reagent-grade which met ACS specifications. Vacuum-dried before use. (3) 18 M Ω water obtained from a Milli-Q Super-Q water system.

AUXILIARY INFORMATION																																																	
METHOD/APPARATUS/PROCEDURE: Two procedures were used for saturating solutions with CO ₂ : <u>Saturation by bubbling (B).</u> The solution was placed in the saturating tube, the lower end of which was connected through a wash bottle with a Kipp CO ₂ generator. The tube and wash bottle were immersed in a constant temperature bath. CO ₂ gas was bubbled through it rapidly for 30 minutes. The wash bottle was replaced by a mercury reservoir and the free gas was driven completely out of the saturating tube by admitting mercury underneath the solution. The CO ₂ contents of the solutions were determined in the manometric gas apparatus (Refs 1 and 2). <u>Saturation in rotating tonometer (T).</u> The technique used was that described by Austin et al. (Ref. 3). Both procedures gave identical results with solutions of acids and salts.	SOURCE AND PURITY OF MATERIALS: (1) From a Kipp CO ₂ generator. (2) Not specified. (3) Not specified. AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref. 1.		(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).		
		(2) DDR pro analysis grade by DDR Standard TGL 5021.		
		(3) Double distilled.		
		ESTIMATED ERROR:		
		Not given.

AUXILIARY INFORMATION					
METHOD/APPARATUS/PROCEDURE: Setchenow (Ref. 1) based his apparatus on those of Fernet (1857) and of Meyer (1857). The manometer was based on ideas he learned from Regnault in 1861. The one meter manometer had three branches, two for measuring the pressure and one a mercury reservoir. The manometer was connected to the absorption cell by a flexible silver capillary. The absorption cell was of two bulbs with a mark in the constricting connection. CO ₂ gas was generated, saturated with water vapor and filled the bulbs and manometer to a known pressure less than atmospheric. The liquid was degassed by heating and then passed by the pressure difference into the lower bulb to the mark of known volume. The system was sealed, turned 90 degrees and shaken until equilibrium was established. The gas volume absorbed was reduced to 0 °C and one meter Hg pressure. The Bunsen coefficient was calculated.			SOURCE AND PURITY OF MATERIALS: (1) Apparently generated from limestone and sulfuric acid. Dried. (2) Not specified. (3) Not specified, assumed to be distilled.		
			ESTIMATED ERROR: The author makes a qualitative statement that the results are good to the second decimal.

<p>AUXILIARY INFORMATION</p>																																																																										
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref. 1.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).</p> <p>(2) DDR pro analysis grade by DDR Standard TGL 5021.</p> <p>(3) Double distilled.</p> <p>ESTIMATED ERROR:</p> <p>Not given.</p> <p>REFERENCES:</p> <p>1. Gerecke, J.; Bittrich, H.J. <i>Wiss. Z. Tech. Hochsch. Chem. "Carl Schorlemmer" Leuna-Merseburg</i> 1971, 13(2), 115-22.</p>

AUXILIARY INFORMATION																	
METHOD/APPARATUS/PROCEDURE: Solutions were made up by weight. Concentration of each solution was verified by measuring the density. (Density was not reported in paper.) A measured volume of gas was brought into contact with a measured quantity of gas-free solvent. Equilibrium was established by agitation using a magnetic stirrer. The volume of remaining gas was measured. The amount of gas absorbed was estimated from change in volume of gas. Details in original paper.	SOURCE AND PURITY OF MATERIALS: (1) From commercial cylinder. Purity 99.8 %. (2) Analytical grade. (3) Distilled and degassed.

AUXILIARY INFORMATION																																											
METHOD/APPARATUS/PROCEDURE: <p>The apparatus is a combination of previous designs (Refs 1 and 2). It was modified to achieve a more accurate determination of the volume of the absorbent liquid. The apparatus measures the volume of absorbed gas as the volume of mercury that must be supplied to the system in order to restore the initial pressure. The raw solubility data obtained are gas/liquid volume ratios. A detailed description of apparatus, method and procedure is given in Ref. 3.</p>	SOURCE AND PURITY OF MATERIALS: (1) Commercial, purity 99.95 mole %. (2) Merck. Grade not given. (3) Distilled and degassed.

METHOD/APPARATUS/PROCEDURE: Either pure CO ₂ gas or CO ₂ -N ₂ mixtures were used in the experiments to maintain a constant $P(\text{CO}_2)$. The CO ₂ -N ₂ mixtures were made by pumping predetermined amounts of CO ₂ and N ₂ into a gas tank and their composition was verified by gas chromatography. CO ₂ or CO ₂ -N ₂ gas mixtures were equilibrated with the aqueous solutions in a series of stirred water-jacketed reaction vessels with condensers. The gas was premoistured by first passing it through distilled water at the temperature of experiment. Fine bubbles were obtained by using gas-dispersion tubes. The bubbling rate was 90 to 95 mL min ⁻¹ . The mole fraction of CO ₂ in the CO ₂ -N ₂ mixture was determined using a Hewlett Packard (5790A) gas chromatograph. AUXILIARY INFORMATION																																																																										
METHOD/APPARATUS/PROCEDURE: The principle of the Ostwald method was used in which the gas is agitated with a measured quantity of gas-free liquid and the decrease in volume of solution-saturated gas is measured in a burette over mercury. The pressure was adjusted to yield one atmosphere partial pressure of carbon dioxide. The volume of gas was reduced to 0°C by the ideal gas law. Experiments were conducted to show that the agitation did not cause super-saturation.	SOURCE AND PURITY OF MATERIALS: (1) Commercial cylinder, 99.8 % pure. (2) Analytical grade. (3) Distilled and degassed.																																																																									
	ESTIMATED ERROR: $\delta T/K = <\pm 0.1$ at 0.2°C, ± 0.03 at other temperatures (authors), $\delta\alpha/\alpha, \delta S/S = \pm 0.002$ (authors).

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:		
The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref. 1.		(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).		
		(2) DDR pro analysis grade by DDR Standard TGL 5021.		
		(3) Double distilled.		
		ESTIMATED ERROR:		
		Not given.

^a $L =$ Ostwald coefficient ($cm^3\ cm^{-3}$)

$P = 1\ atm = 101.325\ kPa = 1.01325\ bar$

AUXILIARY INFORMATION**METHOD/APPARATUS/PROCEDURE:**

Volumetric apparatus with multibulb buret and magnetic stirrer. Amount of solution and gas absorbed determined volumetrically. Density and composition of solution determined after absorption. Details in Ref. 1.

SOURCE AND PURITY OF MATERIALS:

- (1) High purity grade sample, purity 99.96 mole %.
 (2,3) Guaranteed reagent, solution degassed by boiling.

ESTIMATED ERROR:

$\delta T/K = \pm 0.05$; $\delta L = \pm 1\ \%$.

AUXILIARY INFORMATION				
METHOD/APPARATUS/PROCEDURE: The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. For calculation of the Kuenen coefficient, the density of the solution was obtained from Landolt-Börnstein extant 1969. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref. 1.		SOURCE AND PURITY OF MATERIALS: (1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author). (2) DDR pro analysis grade by DDR Standard TGL 5021. (3) Double distilled.		
		ESTIMATED ERROR: Not given.

		METHOD/APPARATUS/PROCEDURE: Two procedures were used for saturating solutions with CO ₂ : <u>Saturation by bubbling (B).</u> The solution was placed in the saturating tube, the lower end of which was connected through a wash bottle with a Kipp CO ₂ generator. The tube and wash bottle were immersed in a constant temperature bath. CO ₂ gas was bubbled through it rapidly for 30 minutes. The wash bottle was replaced by a mercury reservoir and the free gas was driven completely out of the saturating tube by admitting mercury underneath the solution. The CO ₂ contents of the solutions were determined in the manometric gas apparatus (Refs 1 and 2). <u>Saturation in rotating tonometer (T).</u> The technique used was that described by Austin et al. (Ref. 3). Both procedures gave identical results with solutions of acids and salts.	SOURCE AND PURITY OF MATERIALS: (1) From a Kipp CO ₂ generator. (2) K-lactate solutions were made by adding known excess of lactic acid to solutions of KHCO ₃ . (3) Not specified. (4) Distilled. AUXILIARY INFORMATION			
METHOD/APPARATUS/PROCEDURE:		SOURCE AND PURITY OF MATERIALS:	
The prepared solvent and solution were charged into an evacuated cell after degassing, and the mass of solvent was determined by weight. Gas was introduced into the cell from a measuring buret in which the gas was stored over mercury. The cell was agitated while the gas pressure was maintained by adjusting the gas volume. The Ostwald coefficient was determined from the mass of solvent and the volume of gas absorbed. Solubilities were measured at pressures above and below atmospheric.		(1) Source and purity not given. An aqueous "soda" solution absorbed 99.8 % of the gas.	
		(2) Source and purity not given. Recrystallized from water and dried.	
		(3) Boiled to remove carbon dioxide.	
		ESTIMATED ERROR:	
		$\delta T/K = \pm 0.2$; $\delta p/\text{kPa} = \pm 0.1$ $\delta L/L = \pm 0.02$ (compiler)

<p>AUXILIARY INFORMATION</p>																																													
<p>METHOD/APPARATUS/PROCEDURE:</p> <p>The principle of the Ostwald method was used in which a measured volume of gas-free liquid is stirred in the presence of the gas, and its decrease in volume is measured in a burette over mercury. The volume of liquid was measured at the experimental temperature. The molar concentration of salt in the liquid was standardized at 20°C. These data are analyzed and discussed further in Ref. 1.</p>	<p>SOURCE AND PURITY OF MATERIALS:</p> <p>(1) VEB Leuna Works; 99.8 vol %; the impurity was mostly water (author).</p> <p>(2) DDR pro analysis grade by DDR Standard TGL 5021.</p> <p>(3) Double distilled.</p> <p>ESTIMATED ERROR:</p> <p>Not given.</p> <p>REFERENCES:</p> <p>1. Gerecke, J.; Bittrich, H.J. <i>Wiss. Z. Tech. Hochsch. Chem. "Carl Schorlemmer" Leuna-Merseburg</i> 1971, 13(2), 115-22.</p>

(continued on next page)

COMPONENTS: (1) Carbon dioxide; CO ₂ ; [124-38-9] (2) Ammonium chloride Sodium chloride Potassium chloride (3) Water; H ₂ O; [7732-18-5]	ORIGINAL MEASUREMENTS: Mackenzie, J. J. <i>Ann. Phys. (Leipzig) [3] 1877, 1,</i> 438-51.
VARIABLES: $T/K = 279.6 - 295.2$ $p_1/kPa = 93.6 - 101.6$	PREPARED BY: H. L. Clever
EXPERIMENTAL VALUES: (continued) <p style="text-align: center;">AUXILIARY INFORMATION:</p> <p>For ammonium chloride at 288 K and 8.723 mass % the paper gave an average solubility of 0.7906. The compiler's average of 0.7973 is given in the table.</p> <p>The relative density of 22.506 mass % KCl must be a printing error. Comparison with density values in the <i>International Critical Tables</i> leads one to assume the value should be 1.149. The concentration is calculated with the assumption.</p> <p>The compiler calculated and added the Kelvin temperatures, the concentration and molality values and the standard deviations.</p> <p>For values of large standard deviation the compiler has dropped the value with largest deviation and given a second average.</p> <p>These data are of marginal value. Some show a standard deviation as large as 10 %, although many show a standard deviation under 3 %.</p> <p>The author clearly states these are Bunsen coefficients. However, the compiler's analysis of the author's calculations indicates the gas volume was reduced to the partial pressure at equilibrium. If this is true the values need to be reduced from 0 to 7.5 % to the Bunsen coefficients. Tabulated in the paper are pressure and volume of dry gas before equilibration, volume and partial pressure of wet CO₂ gas not absorbed, and mercury volume displaced.</p>	
AUXILIARY INFORMATION	
METHOD/APPARATUS/PROCEDURE: <p>The apparatus consisted of a bulb of known volume in which the initial pressure and carbon dioxide (reduced to 0 °C) was measured; a bulb of known volume for the solvent; and a manometer system to adjust the final volume of the unabsorbed wet gas and measure its total pressure (reduced to 0 °C). The final total pressure of wet gas was reduced to the partial pressure of carbon dioxide by subtraction of the solution water vapor pressure.</p> <p>There was a statement that the carbon dioxide solubility in water was measured, but no solubility values were given.</p>	SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Prepared by action of sulfuric acid on marble. Dried by bubbling through sulfuric acid. (2) Salts. Recrystallized. Solution prepared by weight and checked by evaporation to dry salt. (3) Water. Nothing specified. ESTIMATED ERROR: Temperature: Nothing specified. Solubility: Nothing specified, but see standard deviations in table.

AUXILIARY INFORMATION						
METHOD/APPARATUS/PROCEDURE: The apparatus consisted of a bulb of known volume in which the initial pressure and carbon dioxide (reduced to 0 °C) was measured; a bulb of known volume for the solvent; and a manometer system to adjust the final volume of the unabsorbed wet gas and measure its total pressure (reduced to 0 °C). The final total pressure of wet gas was reduced to the partial pressure of carbon dioxide by subtraction of the solution water vapor pressure. There was a statement that the carbon dioxide solubility in water was measured, but no solubility values were given.				SOURCE AND PURITY OF MATERIALS: (1) Carbon dioxide. Prepared by action of sulfuric acid on marble. Dried by bubbling through sulfuric acid. (2) Salts. Recrystallized. Solution prepared by weight and checked by evaporation to dry salt. (3) Water. Nothing specified.		
				ESTIMATED ERROR: Temperature: Nothing specified. Solubility: Nothing specified, but see standard deviations in table.		

COMPONENTS: (1) Carbon dioxide; CO ₂ ; [124-38-9] (2) Electrolyte (saturated) (3) Water; H ₂ O; [7732-18-5]	ORIGINAL MEASUREMENTS: Passauer, H. <i>Feuerungstech.</i> <u>1931</u> , 19, 142-45. AUXILIARY INFORMATION																																									
METHOD/APPARATUS/PROCEDURE: <p>Absorption of pure CO₂ at 20 °C (293.15 K) was determined in a gas buret type of apparatus. The cm³ of CO₂ absorbed per 100 cm³ of saturated aqueous solution of the salts listed above was measured. The abstract does not make clear if the gas volume absorbed was reduced to standard conditions, however, a reference (1) to this work implies the absorbed gas volumes were reduced to standard conditions.</p> <p>Neither density nor composition of the saturated salt solutions were given.</p>	SOURCE AND PURITY OF MATERIALS: <p>The abstract gives no information on source and purity of the components other than the statement "pure CO₂".</p> ESTIMATED ERROR: <p>No information given in abstract.</p> REFERENCES: 1. Nahoczky, A. <i>Bányász. Kohász. Lapok</i> <u>1933</u> , 66, 332-35.

AUXILIARY INFORMATION													
METHOD/APPARATUS/PROCEDURE: The prepared solvent and solution were charged into an evacuated cell after degassing, and the mass of solvent was determined by weight. Gas was introduced into the cell from a measuring buret in which the gas was stored over mercury. The cell was agitated while the gas pressure was maintained by adjusting the gas volume. The Ostwald coefficient was determined from the mass of solvent and the volume of gas absorbed. Solubilities were measured at pressures above and below atmospheric. AUXILIARY INFORMATION																																											
METHOD/APPARATUS/PROCEDURE: <p>The solubility of CO₂ was determined from pressure-volume-temperature (PVT) measurements using the technique of gas extraction. The apparatus consisted of (1) a high-pressure, high-temperature section for dissolving the gas in the brine, (2) a heat exchanger for cooling (or heating) samples of gas-saturated brine to room temperature, and (3) a low-pressure, constant temperature section for making PVT measurements on collected gas and liquid samples.</p> <p>A two liter, type 316 stainless steel stirred reactor, fitted with a heat- and chemical-resistant glass liner, was filled two-thirds full with brine. The brine was deaerated by evacuating the reactor to the vapor pressure of the brine for at least 3 minutes. Upon reaching thermal equilibrium, the gas was injected into the reactor and allowed to distribute at a fixed partial pressure between the vapor and liquid phases. Equilibration occurred within 5 hours at 150 °C and above, and within 24 hours at lower temperatures. The concentration of CO₂ in the liquid was determined by desorption from a known volume of liquid followed by volumetric analysis of the evolved gas.</p>	SOURCE AND PURITY OF MATERIALS: (1) 99.5 %. (2) Prepared from reagent grade chemicals. (3) Demineralized. ESTIMATED ERROR: $\delta K_H/K_H = 0.058$ (by author) (Detailed analysis of experimental contributions to the total error is given in the source.)

^a Calculated by the compiler.

^b $K_H = P_1\phi_1/x_1$, where K_H = Henry's law constant, P_1 = partial pressure of gas ($P_1 = P - P_2$; P_2 is the vapor pressure of water at the corresponding temperature), ϕ_1 = fugacity coefficient (Smith, J.M. and Van Ness, H.C. *Chemical Engineering Thermodynamics*, McGraw-Hill, New York 1959), and x_1 = mole fraction of the dissolved CO₂.

SYSTEM INDEX

Page numbers preceded by E refer to evaluation texts whereas page numbers not preceded by E refer to compiled tables. Compounds are named as in Chemical Abstracts indexes. Since *carbon dioxide* and *water* are usually two of the compounds they are omitted in the listing.

A

Acetic acid, sodium salt	E120, 309, 310
Acetic acid, trifluoro-, sodium salt	E122, 317
Aerosol OT, <i>see</i> Butanedioic acid, sulfo-, 1,4-bis(2-ethylhexyl)ester, sodium salt	
Aluminium chloride	E96, 180, 365
Aluminium oxide, hydrate	E95, 179
Aluminium sulfate, <i>see</i> Sulfuric acid, aluminium salt (3:2)	
Ammonium bromide	E90, 155, 156
Ammonium chloride	E89, E90, E92, E112, E119, E127, E128, 147-154, 164, 263, 300, 359, 360, 363
Ammonium citrate, <i>see</i> 1,2,3-Propanetricarboxylic acid, 2-hydroxy-, diammonium salt	
Ammonium nitrate, <i>see</i> Nitric acid, ammonium salt	
Ammonium sulfate, <i>see</i> Sulfuric acid, diammonium salt	
Arsenic pentoxide	E93, E94, 169, 170
Arsenic trioxide	E93, E94, 169, 170
Arsenic trisulfide (colloidal)	E94, 171

B

Barium chloride	E98, E104, E105, E113, 216-220, 269, 361-362
Barium iodide	E131, 363
Benzenesulfonic acid, 4-[[4-[dimethylamino]phenyl]azo]-, sodium salt	E120, 312
Benzenesulfonic acid, dodecyl-, sodium salt, mixt. with α -(nonylphenyl)- ω -hydroxypoly(oxy-1,2-ethanediyl)	E131, 367
Butanedioic acid, sulfo-, 1,4-bis(2-ethylhexyl)ester, sodium salt	E131, 366

C

Calcium chloride	E98, E100-E103, E106, E113, E123, E124, E128, 200-213, 266, 328, 330, 361-363, 365, 368, 369
Calcium nitrate, <i>see</i> Nitric acid, calcium salt	
Calcium sulfate, <i>see</i> Sulfuric acid, calcium salt (1:1) (<i>Carbon dioxide</i>)	
Carbonic acid, monosodium salt	E131, 363
Cesium chloride	E130, E131, 357, 358
Cetyltrimethylammonium bromide, <i>see</i> 1-Hexadecanaminium, <i>N,N,N</i> -trimethyl-, bromide	
Chloric acid, sodium salt	E114, 272
Chromic acid ($H_2Cr_2O_7$), dipotassium salt	E131, 364
Chromic acid ($H_2Cr_2O_7$), disodium salt	E131, 363
Copper sulfate, <i>see</i> Sulfuric acid, copper(2+) salt (1:1)	

D

Deuterium oxide, <i>see</i> Water- d_2
Dextrose, <i>see</i> D-Glucose

E

Ethanedioic acid, dipotassium salt	E131, 364
Ethanedioic acid, monopotassium salt	E129, 354
Ethanol	E131, 364

F

- Ferrate(3-)- hexakis(cyano-C)-, tripotassium, (OC-6-11)- E131, 364
 Ferrate(4-)- hexakis(cyano-C)-, iron(3+) (3:4), (OC-6-11)- E98, 189
 Ferric hydroxide (colloidal), *see* Iron hydroxide
 Ferriferrocyanide (colloidal), *see* Ferrate(4-)- hexakis(cyano-C)-,

 Hydrated aluminium oxide, *see* Aluminium oxide, hydrate
 Hydrated ferric oxide, *see* Iron oxide, hydrate
 Hydrochloric acid E85-E87, E93, E111, E123, 135-137,
 169, 170, 261, 327, 365
 Hydrofluoric acid E85, 134

I

- Iron (II) chloride E131, 363
 Iron(III)hexacyanoferrate(II) E98
 Iron(3+)hexacyanoferrate(4-) E98
 Iron hydroxide E97, 185-187
 Iron hydroxide oxide E97
 Iron oxide, hydrate E97, 184

L

- Lactic acid, *see* Propanoic acid, 2-hydroxy-
 Lactic acid, monosodium salt, D-, *see* Propanoic acid,
 2-hydroxy-, monosodium salt, D-
 Lithium bromide E106, E107, 226, 227
 Lithium chloride E105, E106, 221-225
 Lithium sulfate, *see* Sulfuric acid, dilithium salt

M

- Magnesium chloride E98, E99, E131, 190, 191, 363-365
 Magnesium nitrate, *see* Nitric acid, magnesium salt
 Magnesium sulfate, *see* Sulfuric acid, magnesium salt (1:1)
 Manganese sulfate, *see* Sulfuric acid, manganese(2+) salt (1:1)
 Methanamine, *N,N*-dimethyl-, hydrochloride E94, 172
 Methanaminium, *N,N,N*-trimethyl-, iodide E94, 173
 Methanol E103, E106, 213, 225
 Methyl orange, *see* Benzenesulfonic acid, 4-[[4-[dimethylamino]phenyl]azo]-,
 sodium salt
 Molybdic acid, hexa-ammonium salt E131, 364

N

- Nitric acid E88, E111, E112, E127, E128, 145, 262

Nitric acid, ammonium salt	E93, E103, E104, E112, E113, E118, E128, 165-168, 212, 220, 264, 269, 298, 363
Nitric acid, calcium salt	E103, E104, 214, 215
Nitric acid, magnesium salt	E99, E100, 198, 199
Nitric acid, potassium salt	E126-E129, 342-348
Nitric acid, silver(1+) salt	E131, 363
Nitric acid, sodium salt	E119, E120, 301-305
Nitrous acid, sodium salt	E131, 363
O	
Octanoic acid, pentadecafluoro-, sodium salt	E121, 316
P	
Perchloric acid	E86, E87, 138
Perchloric acid, sodium salt	E114, 273
Phenol, sodium salt	E120, 311
Phosphoric acid	E89, E120, E129, E131, 146, 306, 351, 365
Phosphoric acid, monopotassium salt	E129, E130, 349-353
Phosphoric acid, monosodium salt	E120, 306
Phosphoric acid, trisodium salt	E131, 365
Potassium aluminium sulfate, <i>see</i> Sulfuric acid, aluminium potassium salt (2:1:1)	
Potassium bromide	E124, E125, 331-333
Potassium chloride	E122-E124, E127, E128, 318-330, 359, 360, 363
Potassium dichromate, <i>see</i> Chromic acid ($H_2Cr_2O_7$), dipotassium salt	
Potassium dihydrogen phosphate, <i>see</i> Phosphoric acid, monopotassium salt	
Potassium ferrocyanide, <i>see</i> Ferrate(3-)- hexakis(cyano-C)-, tripotassium, (OC-6-11)-	
Potassium hydrogen oxalate, <i>see</i> Ethanedioic acid, monopotassium salt	
Potassium iodide	E125, E126, 334-339, 363
Potassium lactate, <i>see</i> Propanoic acid, 2-hydroxy-, monopotassium salt	
Potassium nitrate, <i>see</i> Nitric acid, potassium salt	
Potassium oxalate, <i>see</i> Ethanedioic acid, dipotassium salt	
Potassium sulfate, <i>see</i> Sulfuric acid, dipotassium salt	
Potassium thiocyanate, <i>see</i> Thiocyanic acid, potassium salt	
1,2,3-Propanetricarboxylic acid, 2-hydroxy-, diammonium salt	E95, 174, 175
1,2,3-Propanetriol	E131, 364
Propanoic acid, 2-hydroxy-	E121, E130, 313, 355
Propanoic acid, 2-hydroxy-, monopotassium salt	E130, 355
Propanoic acid, 2-hydroxy-, monosodium salt, D-	E121, 313
Prussian blue	E98, 189
R	
Rubidium chloride	E130, 357
S	
Sea water	E76-E78, 79-83
Silicic acid (colloidal)	E95, 177, 178
Silver nitrate, <i>see</i> Nitric acid, silver(1+) salt	
Sodium acetate, <i>see</i> Acetic acid, sodium salt	
Sodium bromide	E114, E115, 274-277
Sodium chlorate, <i>see</i> Chloric acid, sodium salt	
Sodium chloride	E108-E114, E119, E124, E127-E129, E131, 232-271, 299, 300, 329, 330, 347, 348, 359, 360, 363-365, 368, 369
Sodium dichromate, <i>see</i> Chromic acid ($H_2Cr_2O_7$), disodium salt	
Sodium dihydrogen phosphate, <i>see</i> Phosphoric acid, monosodium salt	
Sodium dodecyl sulfate, <i>see</i> Sulfuric acid monododecyl ester sodium salt	
Sodium fluoride	E107, 231

Sodium formate, <i>see</i> Formic acid, sodium salt	
Sodium 1-heptylsulfonate, <i>see</i> 1-Heptanesulfonic acid, sodium salt	
Sodium hydrogen carbonate, <i>see</i> Carbonic acid, monosodium salt	
Sodium hydrogen sulfite, <i>see</i> Sulfurous acid, monosodium salt	
Sodium iodide	E115, 278-280
Sodium lactate, <i>see</i> Propanoic acid, 2-hydroxy-, monosodium salt, D- (also Lactic acid, monosodium salt, D-)	
Sodium nitrate, <i>see</i> Nitric acid, sodium salt	
Sodium nitrite, <i>see</i> Nitrous acid, sodium salt	
Sodium perchlorate, <i>see</i> Perchloric acid, sodium salt	
Sodium perfluorooctanoate, <i>see</i> Octanoic acid, perfluorooctanoate-, sodium salt	
Sodium phenoxide, <i>see</i> Phenol, sodium salt	
Sodium phosphate, <i>see</i> Phosphoric acid, trisodium salt	
Sodium sulfate, <i>see</i> Sulfuric acid, disodium salt	
Sodium thiosulfate, <i>see</i> Thiosulfuric acid (H ₂ S ₂ O ₃), disodium salt	
Sodium trifluoroacetate, <i>see</i> Acetic acid, trifluoro-, sodium salt	
Strontium chloride	E98, E104, 361, 362
Sucrose, <i>see</i> α -D-Glucopyranoside, β -D-fructofuranosyl-	
Sulfuric acid	E86-E88, E118, E131, 139-144, 294, 295, 365
Sulfuric acid, aluminium salt (3:2)	E96, 180, 365
Sulfuric acid, aluminium potassium salt (2:1:1)	E130, 356
Sulfuric acid, ammonium iron(2+) salt (2:2:1), hexahydrate	E97, 188
Sulfuric acid, calcium salt (1:1)	E113, 267, 268
Sulfuric acid, copper(2+) salt (1:1)	E96, 182, 183, 364
Sulfuric acid, diammonium salt	E90-E92, E118, E128, 157-164, 296, 297
Sulfuric acid, dilithium salt	E107, 228-230
Sulfuric acid, dipotassium salt	E126, 340, 341, 363
Sulfuric acid, disodium salt	E115-E119, E127, E128, 282-300, 365
Sulfuric acid, magnesium salt (1:1)	E99, E100, E112, E113, E128, E129, E131, 192-197, 265, 348, 364
Sulfuric acid, manganese(2+) salt (1:1)	E131, 364
Sulfuric acid monododecyl ester sodium salt	E121, 314
Sulfuric acid, zinc salt (1:1)	E96, 181
Sulfurous acid, monosodium salt	E115, 281
Synthetic sea water	E76, 79
Synthetic Salton Sea geothermal brine	368, 369

T

Teepol CH 53, <i>see</i> Benzenesulfonic acid, dodecyl-, sodium salt, mixt. with α -(nonylphenyl)- ω -hydroxypoly(oxy-1,2-ethanediyl)	
Tetramethyl ammonium iodide, <i>see</i> Methanaminium, <i>N,N,N</i> -trimethyl-, iodide	
Thiocyanic acid, potassium salt	E130, 356
Thiosulfuric acid (H ₂ S ₂ O ₃), disodium salt	E119, E131, 363, 364
Trimethylamine hydrochloride, <i>see</i> Methanamine, <i>N,N</i> -dimethyl-, hydrochloride	
Tripotassium hexacyanoferrate, <i>see</i> Ferrate(3-)- hexakis(cyano-C)-, tripotassium, (OC-6-11)-	

W

(Water)	
Water-d ₂	E67-E70, 71-75

Z

Zinc chloride	E96, 363, 365
Zinc iodide	E131, 363
Zinc sulfate, <i>see</i> Sulfuric acid, zinc salt (1:1)	

REGISTRY NUMBER INDEX

Page numbers preceded by E refer to evaluation texts whereas page numbers not preceded by E refer to compiled tables. Since *carbon dioxide* ([124-38-9]) and *water* ([7732-18-5]) are usually two of the compounds they are omitted in the listing.

50-21-5	E121, E130, 313, 355

SOLUBILITY DATA SERIES

- Volume 1 H. L. Clever, *Helium and Neon*
Volume 2 H. L. Clever, *Krypton, Xenon and Radon*
Volume 3 M. Salomon, *Silver Azide, Cyanide, Cyanamides, Cyanate, Selenocyanate and Thiocyanate*
Volume 4 H. L. Clever, *Argon*
Volume 5/6 C. L. Young, *Hydrogen and Deuterium*
Volume 7 R. Battino, *Oxygen and Ozone*
Volume 8 C. L. Young, *Oxides of Nitrogen*
Volume 9 W. Hayduk, *Ethane*
Volume 10 R. Battino, *Nitrogen and Air*
Volume 11 B. Scrosati and C. A. Vincent, *Alkali Metal, Alkaline Earth Metal and Ammonium Halides, Amide Solvents*
Volume 12 C. L. Young, *Sulfur Dioxide, Chlorine, Fluorine and Chlorine Oxides*
Volume 13 S. Siekierski, T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Nitrates*
Volume 14 H. Miyamoto, M. Salomon and H. L. Clever, *Alkaline Earth Metal Halates*
Volume 15 A. F. M. Barton, *Alcohols with Water*
Volume 16/17 E. Tomlinson and A. Regosz, *Antibiotics: 1,β-Lactam Antibiotics*
Volume 18 O. Popovych, *Tetraphenylborates*
Volume 19 C. L. Young, *Cumulative Index: Volumes 1-18*
Volume 20 A. L. Horvath and F. W. Getzen, *Halogenated Benzenes, Toluenes and Phenols with Water*
Volume 21 C. L. Young and P. G. T. Fogg, *Ammonia, Amines, Phosphine, Arsine, Stibine, Silane, Germane and Stannane in Organic Solvents*
Volume 22 T. Mioduski and M. Salomon, *Scandium, Yttrium, Lanthanum and Lanthanide Halides in Nonaqueous Solvents*
Volume 23 T. P. Dirkse, *Copper, Silver, Gold and Zinc, Cadmium, Mercury Oxides and Hydroxides*
Volume 24 W. Hayduk, *Propane, Butane and 2-Methylpropane*
Volume 25 C. Hirayama, Z. Galus and C. Guminski, *Metals in Mercury*
Volume 26 M. R. Masson, H. D. Lutz and B. Engelen, *Sulfites, Selenites and Tellurites*
Volume 27/28 H. L. Clever and C. L. Young, *Methane*
Volume 29 H. L. Clever, *Mercury in Liquids, Compressed Gases, Molten Salts and Other Elements*
Volume 30 H. Miyamoto and M. Salomon, *Alkali Metal Halates, Ammonium Iodate and Iodic Acid*
Volume 31 J. Eysseltoová and T. P. Dirske, *Alkali Metal Orthophosphates*
Volume 32 P. G. T. Fogg and C. L. Young, *Hydrogen Sulfide, Deuterium Sulfide and Hydrogen Selenide*
Volume 33 P. Franzosini, *Molten Alkali Metal Alkanoates*
Volume 34 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part I: Non-cyclic Substituents*
Volume 35 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part II: 5-Membered Heterocyclic Substituents*

- Volume 36 A. N. Paruta and R. Piekos, *4-Aminobenzenesulfonamides. Part III: 6-Membered Heterocyclic Substituents and Miscellaneous Systems*
- Volume 37 D. G. Shaw, *Hydrocarbons with Water and Seawater. Part I: Hydrocarbons C₅ to C₇*
- Volume 38 D. G. Shaw, *Hydrocarbons with Water and Seawater. Part II: Hydrocarbons C₈ to C₃₆*
- Volume 39 C. L. Young, *Cumulative Index: Volumes 20–38*
- Volume 40 J. Hala, *Halides, Oxyhalides and Salts of Halogen Complexes of Titanium, Zirconium, Hafnium, Vanadium, Niobium and Tantalum*
- Volume 41 C.-Y. Chan, I. N. Lepeshkov and K. H. Khoo, *Alkaline Earth Metal Perchlorates*
- Volume 42 P. G. T. Fogg and W. Gerrard, *Hydrogen Halides in Non-aqueous Solvents*
- Volume 43 R. W. Cargill, *Carbon Monoxide*
- Volume 44 H. Miyamoto, E. M. Woolley and M. Salomon, *Copper and Silver Halates*
- Volume 45/46 R. P. T. Tomkins and N. P. Bansal, *Gases in Molten Salts*
- Volume 47 R. Cohen-Adad and J. W. Lorimer, *Alkali Metal and Ammonium Chlorides in Water and Heavy Water (Binary Systems)*
- Volume 48 F. Getzen, G. Hefter and A. Maczynski, *Esters with Water. Part I: Esters 2-C to 6-C*
- Volume 49 F. Getzen, G. Hefter and A. Maczynski, *Esters with Water. Part II: Esters 7-C to 32-C*
- Volume 50 P. G. T. Fogg, *Carbon Dioxide in Non-aqueous Solvents at Pressures Less Than 200 kPa*
- Volume 51 J. G. Osteryoung, M. M. Schreiner, C. Guminski and Z. Galus, *Intermetallic Compounds in Mercury*
- Volume 52 I. Lambert and H. L. Clever, *Alkaline Earth Hydroxides in Water and Aqueous Solutions*
- Volume 53 C. L. Young, *Cumulative Index: Volumes 40–52*
- Volume 54 W. E. Acree, Jr, *Polycyclic Aromatic Hydrocarbons in Pure and Binary Solvents*
- Volume 55 S. Siekierski and S. L. Phillips, *Actinide Nitrates*
- Volume 56 D. Shaw, A. Skrzecz, J. W. Lorimer and A. Maczynski, *Alcohols with Hydrocarbons*
- Volume 57 W. Hayduk, *Ethene*
- Volume 58 W. E. Acree, Jr, *Polycyclic Aromatic Hydrocarbons: Binary Non-aqueous Systems. Part I: Solutes A–E*
- Volume 59 W. E. Acree, Jr, *Polycyclic Aromatic Hydrocarbons: Binary Non-aqueous Systems. Part II: Solutes F–Z*
- Volume 60 A. L. Horváth and F. W. Getzen, *Halogenated Methanes with Water*
- Volume 61 C.-Y. Chan, E. S. Gryzlova, K. H. Khoo and M.-T. Saugier-Cohen Adad, *Alkali metal and ammonium perchlorates. Part I: Lithium and sodium perchlorates*
